Glass Which Conducts Electricity.—A Paper by Chas. S. Phillips, read before the Royal Society of Edinburgh and published in the Proceedings, describes the preparation of a conducting glass. Fused sodium silicate conducts fairly well, but becomes moist by exposure to the air and is soluble in boiling water. Attempts, therefore, were made to prepare a glass which would conduct the current and yet would not absorb water, and finally a glass containing 32 parts sodium silicate, 5 parts borax, 0·8 part lead oxide, and 0·2 part of sodium antimoniate was found to have these properties. After boiling this glass with water, it was found that it was practically unacted upon by acids, but conducted a current of electricity fairly well. The specific resistance was found to be 5×10^8 ohms at 20° C., and although this value is high, it is about 1,000 times less than that of ordinary glass at 100° C. Plates of this glass are already in use for the windows of electrometers and electroscopes (a conducting transparent varnish, first introduced by the late Prof. Ayrton and Mr. Mather, has been in use for some years for the same purpose), and fibres have been found sufficiently conducting over their surface to justify their replacing the gold leaves in the latter instrument. A length of glass fibre fixed in position with a small hinge of gold leaf thus affords an extremely sensitive index, the position of which may be accurately read by means of a telescope; instruments of this kind are of especial use in the study of radio-activity.

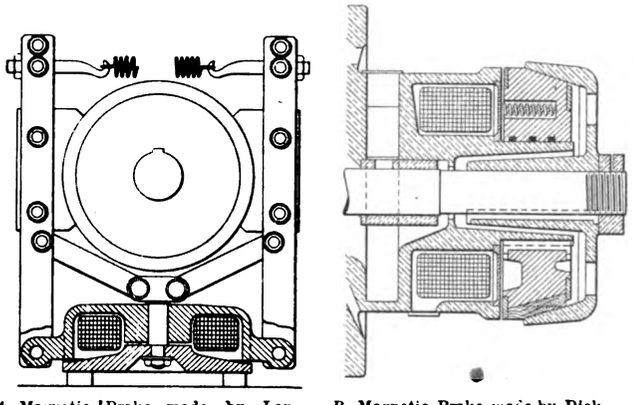
ELECTRICAL EQUIPMENT OF CRANES

A Paper on the electrical equipment of cranes was read by Mr. J. B. Duckitt on Friday last before the North-East Coast Institution of Engineers and Shipbuilders, at Sunderland. In introducing his subject, the author mentioned the principal advantages claimed for electrically-driven cranes, which are as follows:—(1) high over-all efficiency; (2) crane only absorbs power when actually doing work; (3) increased safety; (4) greater flexibility; and (5) higher speed of the various motions. Against these claims must be placed the extra cost and upkeep of the electrical equipment.

Speed of Cranes.—There has been, said the author, a tendency during the last few years to increase the speeds of the various motions, but this has not always proved wise. In the first place, higher speeds necessitate the fitting of larger motors, and this means an increase in the starting current. Again, larger motors take longer to attain maximum speed, and where the range is small, the motor may never reach its maximum speed or only attain it for a very short time, resulting in a reduction of the efficiency.

Motors.—As all crane motors are subjected to variable loads, it is essential that the fixed losses should be small and the variable losses large, as motors designed in this way have a high efficiency over a large range of load. Though shunt motors are occasionally fitted, the series motor has been almost universally employed on account of its wide range of speed and torque, and also the loss due to field excitation is a component of the variable losses which increases the efficiency at light loads. The totally enclosed type of motor has proved the most suitable, as dirt and damp are excluded and the electrical portions are effectively protected from mechanical injury. A disadvantage of this type is that slight faults developing in the electrical portions of the motor cannot be observed and often serious damage ensues before attention is drawn to them.

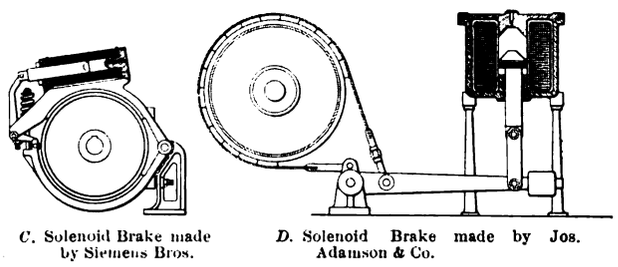


A. Magnetic Brake made by Lancashire Dynamo and Motor Co. *B.* Magnetic Brake made by Dick, Kerr & Co.

FIG. 1.—TYPES OF MAGNETIC BRAKES.

Constructional Details.—Armature shafts should be designed on liberal lines owing to the heavy torsional strains to which they are subjected by being constantly reversed, and the heavy overloads and excessive vibration to which they are liable. The bearings should be of gun-metal or phosphor bronze and provided with self-lubrication. Where the diameter is increased they can be made much shorter than is the usual practice; this, as the over-all length of the motor is reduced, results in a more compact design of crab. Armature core-plates should be stamped out of one sheet, with the air vents stamped in them and the core-plates carried down to the spindle so as to decrease the number of mechanical joints; where spiders are necessary care should be taken that they are perfectly rigid upon the shaft and keys, and also between the discs and arms. Two-circuit or series winding should be adopted for the armatures, because inequality in the lengths of the air-gaps does not affect the satisfactory running of the motor, as equal voltage is induced in both circuits of the armature; whereas with multiple-circuit or parallel winding, unless the armature is central, the various sections of the winding will have unequal voltages, and heating and sparking will result. The commutator lugs should be carried up solid, and the commutator should have a large number of sections in order to keep down the reactance voltage and allow of fixed brushes for all loads. In the design of the brush-holders, the number of screws, nuts, springs, and parts liable to work loose, should be reduced to a minimum. Brush-quadrants when fitted should be very firmly secured; a good method is to fix the brush-holders direct to the end cover, connection being made to them from the outside.

Rating of Motors.—Most makers of crane motors specify the b.h.p. of the motor on a continuous run of one-quarter, one-half, or one hour for a specified rise of temperature. This method has not always proved satisfactory in the case of one-quarter hour rated motors, as the rise of temperature due to overloading increases very rapidly in the armature and field-coils, and they burn out before it has had time to spread to the other portions of the motor. It is therefore inadvisable to adopt motors of less than one-half hour rating. Another system of rating motors for intermittent work, called the "load-factor" method, has been adopted by Messrs. Siemens Bros. The factor of most importance in selecting a motor for intermittent work is the ratio between the working period and the time occupied for a complete cycle of operations; this latter ratio is termed the "load-factor." Messrs. Siemens find that basing the output of the motors on a twelve minutes' cycle gives satisfactory results. "Load-factors" are expressed as $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, and so on, and mean that the motor is running under full load for $\frac{1}{2}$, $\frac{1}{3}$, or $\frac{1}{4}$ of the total time occupied for a complete cycle of operations; with a twelve minutes' cycle the load periods are 6, 4, 3, 2, and $1\frac{1}{2}$ minutes respectively. The motors are designed to give the specified temperature rise when run intermittently under full load for six hours at the various "load-factors," that is, at $\frac{1}{4}$ "load-factor" the motor would be run under full load for three minutes out of every twelve minutes, the test extending over a period of six hours.



C. Solenoid Brake made by Siemens Bros. *D.* Solenoid Brake made by Jos. Adamson & Co.

FIG. 2.—TYPES OF SOLENOID BRAKES.

Speed of Crane Motors.—In deciding the most suitable speeds for the motors the speed at full load has not only to be considered, but also the acceleration of the armatures at light loads on the various motions. The ratios of the speed increase from full load to light on overhead travelling cranes are for the hoisting motion about 3 to 1, for the traversing motion 2 to 1, and 1·5 to 1 for the travelling motion. It is essential that the "no-load" speeds should come well within the safety limit, particularly in the case of the hoisting motor, as the speed when lowering with load may be much higher than when hoisting light. The permissible maximum speeds at normal load for a 9 in. armature are about 450, 600, and 720 r.p.m. for hoisting, traversing, and travelling respectively, and about 340, 450, and 540 r.p.m. respectively for a 16 in. diameter armature.

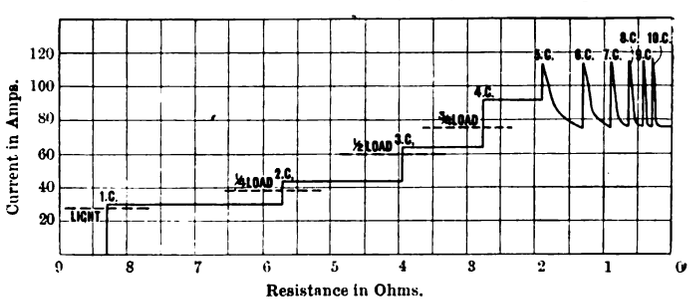


FIG. 3.—DIAGRAM OF DEVELOPMENT OF HOISTING RESISTANCE AND STARTING CURRENT.

Brakes.—Electrically released brakes are usually fitted on the motor spindle and may be divided into two classes, magnetic and solenoid. In the magnetic type the brake is released by an electro-magnet, the pull of the magnet opposing the pressure exerted by springs. Examples of this type are shown in Fig. 1. It is very compact and powerful, but it needs careful adjusting, for should the gap become too great owing to wear, the brake will not be released on light loads. In the solenoid type the plunger is usually connected to a lever to the other end of which

Digitized by Google

is coupled the brake arms or strap. It is essential that this type should have a dashpot connected with the plunger to prevent hammering and shocks to the motor and gear when it is released. Fig. 2 shows examples of this type of brake. The brake coils are either shunt or series wound. When shunt wound they involve extra contacts in the controllers and extra wiring on the crane, and are not so safe as when series wound. The brake magnets should be designed to release when starting with light loads, but at the same time care has to be taken that they do not release too soon or the load may start lowering. It is best to design the brake so that it will release when the

FIG. 4.—DEVELOPMENT OF DRUM CONTROLLER FOR COMPOUND MOTOR WITH REGENERATIVE CONTROL WHEN LOWERING.

pull on the armature of the motor is sufficiently strong to hold the load.

Controllers.—Liquid controllers are cheap and simple to design, and there is no sparking and burning of contacts. The disadvantages are polarisation of the plates, the necessity of short-circuiting the tank to cut out the resistance entirely, the difficulty of effectively insulating the tank, and corrosion due to the solution. The percentage of chemical in the liquid should be carefully regulated for different voltages or sudden rushes of current will occur when starting or short-circuiting. Another objection is that where large power motors are used the tank becomes very heavy. In face-plate controllers the large number of contacts permit of a greater subdivision of the resistance and tend to smooth starting and better regulation of the motor. The leading objections to this type are the difficulty of fitting an effective blow-out, also the contacts and contact arms are not usually enclosed. The drum or tramway controller is totally enclosed, a powerful magnetic blow-out can be easily and effectively fitted, and the various connections for different systems of control can be easily carried out. The leading disadvantages are that few regulating steps in the resistance can be fitted, and that the resistances are not self-contained. The various sections of the resistance must be in the form of a geometrical progression, the extremes of which are the total resistance necessary and the resistance of the motor, which are known quantities. Generally the maximum starting current ranges from 1·5 to twice the normal full-load current, and the hoisting motor resistance is designed to give a reduction of from 0·3 to 0·6 times the normal full-load current, according to requirements, on the first step; for traversing these figures are usually 0·5 to 0·6, and for travelling and slewing 0·5 to 0·75. Fig. 3 shows the development of the resistance for a 20 b.h.p. hoisting motor at 250 volts.

Rating of Controllers and Resistances.—Controllers, like motors, are designed for intermittent working. It is found that doubling the capacity of the controllers for continuous rating, and making the period of work to period of rest as 1 : 1, and the time limit from two to five minutes for resistances, will generally meet the requirements for crane work satisfactorily.

Electrical Control of Lowering.—The use of mechanical brakes can be obviated by so designing the controller that the energy

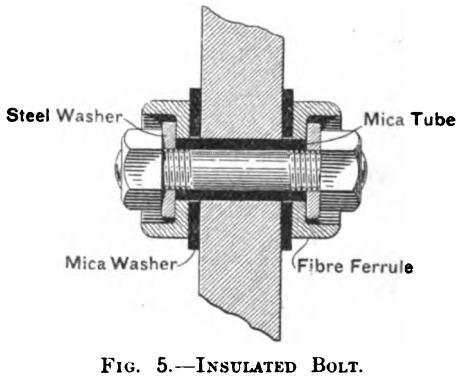

FIG. 5.—INSULATED BOLT.

exerted by the load falling is used to convert the motor into a generator; the electric power so developed being absorbed by short-circuiting it through the resistance. This method of lowering gives complete control over the speed with light or heavy loads, does not throw excessive strains on the gearing, and is much cheaper than fitting mechanical brakes.

Methods of Increasing Efficiency.—The rheostatic method of control is always adopted for crane motors; though simple, effective, and reliable, it is very wasteful. Series-parallel control cannot be adopted for the hoisting motion on cranes, as when hoisting with load the motor would have no inertia to assist it over the transition points when changing from series to parallel. In the case of travelling motions for large cranes the ordinary series-parallel control could be adopted, and the objection to fitting two motors surmounted by fitting one motor with a double armature, and, if requisite, double-field windings.

Regenerative Control.—In the author's opinion the adoption of motors with compound field windings for hoisting motions, controlled in such a manner that when hoisting they act purely as series motors, with the shunt winding entirely cut out, and when lowering as shunt motors, with the series windings cut out, and the regenerative effect utilised, would give an ideal system of control for this motion, as it would result in economy in current consumption, and would give absolute control over the speed of lowering. The disadvantages are that the size and cost of the motor would be somewhat greater on account of the extra field windings and higher rating, it would be necessary to drive down the hook and very light loads by passing the main current through the armature, and the solenoid brake would have to be either shunt or compound wound. Fig. 4 shows the development of this system.

Wiring Details.—The size of cables or wires for the various motions can safely be based on 1,500 amperes per square inch for normal full load. Cables should be protected against oil and dirt by running them in steel conduit or iron piping. A main double-pole enclosed switch should be fitted in the cage. Enclosed fuses, rated to blow at not more than twice the normal full-load current of the motor, should be provided. Sliding contacts give more satisfaction on overhead travelling cranes, as the grit in most works causes trouble with trolleys. The

Digitized by Google

contact shoes should be of soft gun-metal and easily and quickly replaceable. Switches for the prevention of over-winding should be fitted on all cranes to break the circuit when the block reaches a minimum safe distance from the barrel. Limit-switches are also sometimes used to prevent the travelling and traversing motions from running against the stop-blocks, but they are objectionable when it is desired to work the crane as near as possible to the extreme limit of these motions. Nothing but porcelain or mica is permissible for insulating purposes; fibre should never be used except as a further protection to the insulating medium, in which case it will often prove useful and effective when insulating bolts or studs which are connected to current-carrying apparatus. Fig. 5 gives an example: the mica is used as the insulating medium, and the fibre ferrules prevent oil and dirt from bridging it and causing a burn-out.

Polyphase Motors.—Although they lack the chief characteristics which make the continuous-current motor suitable for crane work, polyphase motors are sometimes used; but they should be avoided when possible.

DEPRECIATION AND OBSOLESCENCE IN SMALL ENGINEERING WORKS

By W. O. Horsnaill

IN addition to the stock of material and finished parts which should not be subject to depreciation, the assets of an engineering works consist of machine tools, power plant, distributing gear, lifting appliances, patterns, drawings, buildings, &c., upon all of which items depreciation must be allowed before the true net profits from the undertaking can be arrived at.

In a large concern, which can afford to employ a first-class engineer, the proper allowances for depreciation, and the problems in connection with the scrapping of obsolete machinery, can be settled in the most effective manner with the assistance of a good independent accountant. The engineer for such an undertaking is able not only to estimate closely the useful life of each appliance and to keep himself posted in the very latest practice, but he will introduce original designs and methods to meet competition from similar developments in the works of trade rivals.

These qualifications involve a salary which cannot be paid by a small firm; consequently the latter must either call in outside assistance from time to time or content themselves with inaccurate accounts and out-of-date equipment.

As regards depreciation, very loose methods of estimating this charge are used in many small undertakings; not unfrequently the value of the whole plant is totalled up and written down in one account, the results being more or less accurate according to the knowledge and experience of the accountant. Such a plan cannot be considered satisfactory, neither is it in keeping with the care which is now taken to ascertain the costs of production.

The plant must be considered in detail, and no one but an engineer, well versed in the most modern practice, can estimate the proper allowances for depreciation. The usual method of effecting the latter operation involves a ledger account for each section of the equipment, which is credited with the value of the machinery or appliances referred to. Thus, if a new lathe were installed, a works order would be issued in the ordinary course, to which the cost of purchasing and fixing should be charged, the total being abstracted to the plant ledger account. This account is also credited with any new accessories which may be bought from time to time, and at the end of each year depreciation is charged, and the balance brought down as representing the present value of the lathe.

The system is extended to include all valuable loose tools, such as stocks and dies, reamers, &c., which are kept in the tool-room and lent to the workmen in response to signed receipts or brass tool checks, an account being kept for each different class of tool.

The allowances for depreciation are made at the end of each year, the revised values being carried forward. In estimating these charges the useful life must be considered, together with the residual value and the probability of early replacement becoming advisable owing to the introduction of more efficient appliances.

This question of turning out good plant in favour of more economical machinery is of very great importance, and the firm who takes immediate advantage of new developments in this way is likely to benefit by them to a much greater extent than competitors who wait until the new appliances are in general use before making the change. There are two reasons for this state of things:—Firstly, the residual value of the old machinery is much higher when sold before the new methods have made headway; secondly, the price of the product will not be reduced in proportion to the lower cost of manufacture until the more efficient means have been largely adopted.

In this connection it may be remarked that the concern in which new machines or devices for cheapening production are continually being invented has a great advantage over its rivals who only adopt new methods when placed upon the market by others. Such a concern can obtain good prices for its old machines as the latter *appear* to be up-to-date to less enlightened competitors.

In the manufacture of machinery, perhaps more than in other industries, development is continually going on, and there is no reason to suppose that finality will ever be reached. Such being the case, it would seem imperative that some allowance for this feature of obsolescence be made in the charge for depreciation, a short life, and a high residual value being substituted for the assumption that a machine will be worn out and finally scrapped.

In view of the rapid changes being made in engineering methods, a life of ten years for machine tools is long enough, but, provided immediate advantage be taken of new contrivances, the residual value (excluding erection) should be, say, a third of the first cost, where the plant has been carefully maintained. Many tools will retain their efficiency for a much longer period than that specified above; on the other hand, new machines may be brought out for replacing existing plant which has only been in use for two or three years.

The same principles apply to drawings and patterns, both of which depreciate very rapidly. The value of drawings depends very much upon the class of business being done. Drawings of standard products cannot be expected to possess any value after machines or appliances have been made to them for two or three years, as by that time new designs must be got out if the undertaking is to keep going forward, the days being passed when the same article or machine could be manufactured year after year without modification. If improvements are not demanded by the users, competition compels a reduction in price, involving more economical designs to enable profits to be made.

Patterns are similarly affected, and their value, as regards those constructed of wood, is still further reduced by wear and tear. It is an open question whether drawings and patterns can, under modern conditions, be deemed to possess any appreciable value, but if they are to be treated as an asset, depreciation must be based on a very short life and a scrap residual value; further, it is imperative that the stock must be looked over every twelve months by an engineer who is competent to write off patterns and drawings which have become obsolete.

It may be contended that customers will sometimes insist upon being supplied with an old design to which they have become accustomed, but this feature is being gradually eliminated under modern conditions. At one time articles or machines were made up singly or in small numbers to suit customer's requirements, and the prices were very much higher than is the case at present for similar products manufactured by special tools and in large quantities. Consequently when a customer asks for old designs he has to pay the old prices, which can seldom be afforded.

Drawings and patterns for very large machines or appliances which are constructed in response to special orders will have been allowed for at their full value in the cost of production, and although they may be kept for years, the chances of their being used over again are too remote to justify their inclusion amongst assets.

The power plant and distributing gear are open to the similar influences to those we have described in connection with machine tools. It is not impossible that shafting may be almost entirely superseded by electric motors before another decade has passed away. These possibilities can be allowed for in the charge for depreciation, which should not be less than 7½ per cent. for power plant and transmission gear.

It might be supposed that brick buildings, if carefully maintained, would not be subject to depreciation, but here, again, the

Digitized by Google

question of improvements comes in, and experience tells us that modification to the equipment entails alteration to buildings, hence a yearly allowance of, say, 5 per cent. should be deducted from the value of the latter to cover expenditure in this direction. Buildings into the construction of which steel largely enters must be specially considered, a larger allowance being set aside to cover the deterioration of this material.

Some authorities advocate the setting aside of a reserve fund to cover the replacement of machinery which has become obsolete before being worn out, the allowance for depreciation being based upon the useful life of the plant when carefully maintained. Such a fund is often contributed to liberally during successful periods, and there is a temptation (not always resisted) to draw upon it when trade is bad, for the purpose of paying dividends which have not justly been earned. In the writer's opinion, the inclusion of obsolescence in the allowance made for depreciation is a simpler and more correct method, the provision for replacing out-of-date plant being just as essential as the renewal of machinery which is actually worn out.

Moreover, it is clearly understood that arrears of depreciation must be paid off before profits are made, whereas the setting aside of a sum out of revenue in favour of the reserve fund does not appear to be so imperative. Hence when this system is adopted, although what may be called ordinary depreciation is properly allowed for, the equally essential feature of obsolescence may not receive the attention it deserves.

The percentages for depreciation given above cannot be looked upon as rules to be adhered to when determining such charges, the figures being only specified to illustrate the principles put forward.

It is impossible to lay down definite rules for depreciation as the conditions are continually changing, and the first cost may have been much too high in view of subsequent developments. The most accurate method of obtaining correct results is to have the plant valued by an independent engineer every few years, supplemented by an annual inspection, the rates for the next few years being fixed at each valuation. This duty may be carried out by the manager or principal in a small undertaking, but the results are not so satisfactory, there being generally a lack of knowledge regarding the most modern practice, together with a natural tendency to cut down the rates for the purpose of showing a better profit.

THE PROPOSED TAX ON ELECTRICITY IN GERMANY

IN last week's issue we published an abstract of the Bill which has been introduced by the German Government, in which a tax on electrical energy, gas, and illuminating apparatus is proposed. There is considerable opposition to the Bill, and in engineering circles the proposals are being eagerly discussed. There is little doubt some formal protest will be presented to the Government from the representatives of the industries concerned. A special meeting of the Elektrotechnischer Verein will be held in Berlin this evening, when Herr G. Dettmar (General Secretary of the Verband Deutscher Elektrotechniker) will open a discussion on the subject. Owing to the importance of the matter an unusually large attendance of the representatives of the electrical industry is expected.

With regard to the influence of the tax on the electrical industry, the following figures, which are taken from a letter written by the director of a large iron works in the Lower Rhine district and published in the *Elektrotechnischer Anzeiger*, afford a striking example of the heavy nature of the proposed tax. The works in question has a generating plant in connection with its blast furnaces, which supplies the whole of the works with power and light. The yearly output of the station at present amounts to 28 million units, and when the proposed extension of electric driving to all the rolling-mills will have been completed, the output will be about 35 million units.

Now according to the provisions of the tax (see ELECTRICAL ENGINEERING, November 19th, page 677), energy for the use of the producer is to be taxed uniformly to the amount of 5 per cent. of the total generating costs. With the total costs in the works at 2·5 pfennig (0·3d. per unit), this amounts to a total sum of 43,750 marks per annum (approximately £2,150). To this also must be added the tax on lamps. From the works' records 5,500 lamps, on which a tax of 30 pfennigs is to be imposed, and 1,500 lamps with a proposed tax of 50 pfennigs, were used in the past year. This amounts to a total tax on lamps of 2,400 marks (approximately £120). Some 8,000 kg. of arc lamp carbons were consumed during the year, and with a tax of 1 mk. per kg., this means 8,000 marks (approximately £400). Thus the annual sum which will have to be paid out if the proposed tax becomes law will amount to 54,150 marks (approximately £2,670), or over 1 per cent. of the share capital of the company. The writer concludes that it the tax becomes law, the company will regret that they did not continue to use steam as the driving agent in the works.

It is interesting to compare the relative values of the revenues expected from the new sources. These are as follows:—Spirits, £5,000,000; tobacco, £3,850,000; beer, £5,000,000; wine, £1,000,000; death duties, £4,600,000; electricity and gas, £2,500,000 (the relative amounts expected from the different items were given on page 678 of our last week's issue); and from the tax on advertisements, £1,650,000. These total up to some £23,600,000, of which it is seen that over 10 per cent. is to be contributed by electricity and gas.

The taxes on electricity and on illuminating apparatus are not the only proposals which will affect the electrical industry. The proposed company tax, which is to apply to Prussia only, will have a far-reaching influence if passed. In cases of affiliated companies, it is said that the tax will be imposed more than once, and this will have the effect of bringing up its amount from 6 to 7 per cent. of the net profits to as much as 20 per cent. under certain conditions. With respect to the above, it is interesting to note that the Deutsche-Ueberseeischen Elektricitäts-Ges., of Berlin, and the Elektrische Licht- und Kraftanlagen Akt.-Ges. have both decided at meetings held recently that, in the case of the proposal becoming law, the official offices of the respective companies should be established outside Prussian territory, and the latter company also decided to abolish its subsidiary companies who have official offices in Prussia.

Troubles with Overhead Equipment.—According to the *Railway Gazette*, the New York, New Haven & Hartford Railway's overhead contact line construction, which was designed particularly for rigidity, has given considerable trouble because it was too successful in this respect. It is on the double catenary suspension system, two upper steel messenger wires being connected to the lower copper wire, with which the sliding-bow comes in contact, by triangular trolley-hangers spaced 10 ft. apart. The sliding-bow strikes these points of support a heavy blow, and the triangles are so stiff that breakages result, as well as excessive vibration throughout the structure and a great deal of sparking. To remedy this, another wire has been strung an inch or two below the old contact wire, being hung from it at points half-way between the triangles. The sliding-bow touches this wire only, and the blows at its points of support are cushioned in transmission to the rest of the structure, instead of striking directly the stiff triangles. This has proved so successful that the overhead construction has now been modified in this way over a considerable length of track.

Audible Signalling on the Great Western Railway.—On page 431 of ELECTRICAL ENGINEERING, Vol. I., we gave a full illustrated description of the Great Western Railway Co.'s system of audible distant signals, in which a third rail a few yards long is provided at each signalling point, with which contact is made by a shoe on the locomotive. When the signal "clear" is to be given, the current picked up causes a bell to ring in the locomotive cabin, but if the contact rail is not connected to the battery in the signal-box, the plunger carrying the contact shoe is caused to interrupt a local circuit and release a whistle valve, which is normally held closed. According to the *Railway Times*, this system has given so much satisfaction on the Witney and Fairford line, that a further extension has been decided upon, and the four main lines of the Great Western Railway between Reading and Slough are being equipped for working on this system. There will be sixty-six signalling ramps on this section of the line. An improvement in the cab apparatus has been effected, in that only one electromagnet is used, a polarised relay serving, when energised by the current picked up from the ramp, to keep the local circuit on the engine closed. The Lambourn Valley branch of the Great Western is also to be equipped on this system.

The Junior Institution of Engineers.—The inaugural address delivered by Mr. J. Swinburne to the Junior Institution of Engineers on Tuesday, November 17th, consisted of a lucid exposition of the theory of the ideal heat engine and of the notion of entropy. Mr. Swinburne employed metric units, the "barad," or one megadyne per square centimetre, which is almost exactly equal to one atmosphere, being the unit of pressure, and the joule the unit of energy. The ordinary thermal unit, involving the specific heat of water, was, said Mr. Swinburne, of no use; it belonged to the days when people had not fully realised that heat was energy. After carefully explaining the notion of entropy and the true meaning of the $\Theta\Phi$ diagram, Mr. Swinburne concluded by stating that a study of the kinetic theory of gases afforded a means of obtaining a physical conception of the notion of entropy, and enabled a student to get a good mental hold of the principles of thermodynamics. The kinetic theory of gases was, in fact, one of those main roads of knowledge from which it was always easy to branch out into any particular study.

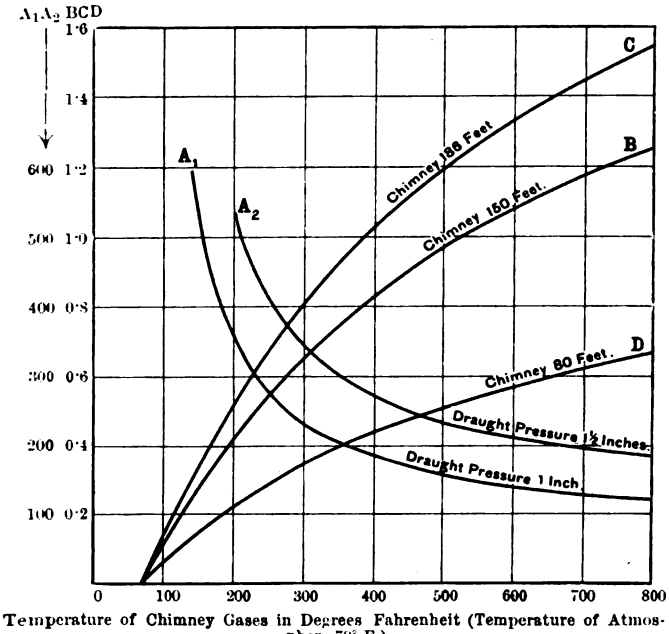
A COMPARISON OF NATURAL AND INDUCED DRAUGHT SYSTEMS

AT a meeting of the Leeds Local Section of the Institution of Electrical Engineers yesterday, Mr. W. N. Y. King read a Paper comparing the merits of natural and induced draught for steam-raising plant. In his introductory remarks he stated that in steam-raising plants, as commonly installed and operated with natural draught, the discharge to waste in the atmosphere of a large volume of gas at high temperature represented in many cases a loss of as much as 20 to 25 per cent. of the total available energy of the fuel. Of the two systems of mechanically-produced draught, the "Induced Draught," in which the boiler furnace outlet is connected to the fan suction chamber, is the only one dealt with in this Paper, on account of its many advantages, for land purposes, over the other, namely, the "Forced Draught," in which the fan discharges air into the furnace inlet, a system which has been more adapted to marine purposes, though latterly it has been combined with underfeed stokers on land in some instances.

The curves, A_1, and A_2, (Fig. 1) show the height of chimney required to produce one inch, and one-and-a-half-inch draught pressure respectively, with different values of chimney gas temperatures. Curves *B*, *C*, *D* show how the draught pressure varies with the chimney temperature for heights of 150, 186, and 80 ft. respectively. The atmospheric temperature is assumed to be 70° F., and barometer normal, in all cases. Under



Temperature of Chimney Gases in Degrees Fahrenheit (Temperature of Atmosphere 70° F.).
Curves A_1 A_2. Height of Chimney in Feet.
Curves B C D. Draught Pressure in Inches of Water.

FIG. 1.—NATURAL DRAUGHT CURVES.

ordinary working conditions the draught indicated by gauge at the base of a chimney is about 5 per cent. less than the theoretical value on account of this proportion of the pressure being counteracted by the friction of the gases in the chimney, and a corresponding allowance must be made when referring to the curves if gauge pressure at the chimney base is being considered. The draught pressure, the author explained, determines the available rate of air supply to the furnace, and through this the rate of fuel consumption, so it is obvious that the height of a chimney is its most important dimension, and when this has been decided upon in any case, the area remains to be calculated sufficiently large to deal with the maximum volume of gases it will be required to discharge in a given time, without excessive loss due to friction or to the velocity of the gases leaving the chimney. It is usual practice in this respect, he added, not to exceed a maximum velocity of about 16 ft. per sec., in any part, for above this value the friction losses become excessive, and, as a rule, 10ft. per sec. is a good working velocity.

The author next proceeded to make a comparison in efficiency between natural and induced draught. To represent the latter, the particular case was taken of two Stirling water-tube boilers of the five-drum type, built together in one casing, and one motor-driven fan with a short chimney, to serve both boilers working simultaneously at their maximum output. Table A gives some of the more important particulars of the boilers, and table B those of the fan and motor. Table C gives results which were obtained with one boiler working under normal conditions during a period of six hours. As the two boilers are identical in construction and working, the output of the combined plant was taken as double that in the table. Table D shows the relations existing between the draught shown by gauge at fan intake and the power, speed, &c., of the motor when working on both boilers.

Table A.

Type of boiler	Stirling water tube	(5 drums; Babcock and Wilcox Chain Grate Stoker; style 5.)
Heating surface, each	3,450 sq. ft.	
Superheating ditto ...	188 ,,	
Grate area	59·5 ,,	
Working pressure ...	165 lbs. per sq. in.	
Evaporative capacity	12,500 lbs. per hour from and at 212° F.	

Table B.

FAN:	*Type*	Davidson's Sirocco	
	Capacity ...	45,000 sq. ft. per min.	Against 2½ ins. water pressure
MOTOR:	*Type*	Crompton 4-pole	
	Speed ...	300-600 r.p.m.	
	Power ...	35 B.H.P.	

Table C.

Coal consumption ...	1,232 lbs. per hour	(Washed nuts.)
Water evaporated ...	11,700 lbs. ,,	(Equivalent to 14,860 from and at 212° F.)
,, ,, ...	9·5 lbs. per lb. coal	(Equivalent to 12·06 from and at 212° F.)
Superheat, average ...	100° F.	
Feed water, temperature	42° F.	
Flue gas, temperature...	439° F.	(At fan intake.)
Draught press., by gauge	1·04 ins. of water	,, ,,
CO_2	13 to 14 per cent.	(Leaving the furnace.)
Thickness of coal feed...	4 ins.	
Speed of grate (approx.)	4 ins. per min.	

Table D.

1	14	540	7·56	262	0·88
3	15	540	8·1	292	1·1
5	17	540	9·2	330	1·25
10	20	540	10·8	396	1·6
20	40	540	21·6	528	2·8

The maximum temperature of the furnace gases is assumed to be 2,800° F. (regarding this Messrs. Booth and Kershaw, in a Paper read before the Institution of Electrical Engineers in January 12th, 1905, said that: "The theoretical temperature attainable in the furnace by the combustion of coal lies between 3,500° F. and 3,700° F.; the maximum attained under practical conditions is about 2,800° F.") and the atmospheric temperature is taken to be 70° F.

With this assumption, the author made the following calculations:—The percentage loss of total available furnace heat, with gases leaving the boiler and entering the fan at 439° F. (Table C) is:—

$$\frac{(439-70)\times 100}{2{,}800-70}=13{\cdot}5 \text{ per cent.}$$

A further loss has to be debited to the fan on account of the energy taken by the motor, and from Table D it is found that the power taken to produce the draught of 1·04 in. is just under 8·1 kw. for the two boilers, or for one hour, 8·1 kw.-hours is the energy used. Assuming the coal equivalent as 4 lb. per kw.-hour, the fan takes 32·4 lbs. of coal for the combustion of 2,464 lbs., or 1·31 per cent. of the total. However, this loss is taken into account later in the running charges, and need not be further considered here.

Now, taking the case of a natural draught chimney with the same temperature of gases at the inlet as in the fan intake just mentioned, and allowing 5 per cent. for loss of pressure in friction, the theoretical draught pressure to be produced is 1·1 inches of water, hence the height of chimney required is:—

$$H=\frac{P}{7{\cdot}6\left(\frac{1}{T_2}-\frac{1}{T_1}\right)}=186 \text{ feet,}$$

where T_1 is the mean temperature of the internal gases, and T_2 the temperature of the atmosphere, both expressed in absolute

Digitized by Google

degrees Fahrenheit, and this will give the same heat loss in chimney gases as the fan plant.

The volume of gas discharged is :—

$$\frac{2,464 \times 18 \times 12{\cdot}5 \times 899}{60 \times 60 \times 492} \text{ cu. ft. per sec.} = 282 \text{ cu. ft. per sec.}$$

allowing 18 lbs. of air per lb. of coal.

The area of chimney to deal with this volume at 10 ft. per sec. is 28·2 sq. ft., or for a circular section, the internal diameter must be 6 ft.

The author continued :—.

In connection with the temperature of the gases leaving the boiler, it is to be noted that no air-heater or economiser was in use with the fan system, though the reduction of temperature in that way would have been an entire gain. With natural draught, on the other hand, the temperature could not be reduced on account of the necessity of maintaining the draught pressure. The advantages of an economiser by way of reduced flue gas temperature are principally obtained when the plant is worked below the normal full-load capacity of the chimney; at such a time the economiser takes up heat in a useful way, so that the boiler and furnace may be worked at a relatively high and efficient temperature, while the chimney has a relatively lower temperature corresponding to the smaller draught pressure required. As a source of hot feed water in preference to cold for the benefit of the boilers, an economiser is, of course, equally advantageous to both natural and induced draught plant. The limit to the reduction of gas temperature in fan plant is set by the cost of installation and maintenance of heaters for air and water supply to the boilers, and up to the present time it seems questionable economy to carry the reduction lower than about 350° F. This leaves a considerable margin for improvement down to the ideal limit of the atmosphere. For example, if a temperature of 300° F. is obtained, the heat losses become, in the instance considered, 8·5 per cent., which, with the addition of 1·3 per cent. for fan power, makes the total loss in question 9·8 per cent. only

In the design of a power station, the space occupied by different types of plant is an important consideration, and more particularly so in the boiler-room, because, in consequence of the use of high-speed electric generating machinery concentrating large power units in a small space in the engine-room, there has grown a corresponding difficulty in so laying out the steam-raising units as to keep the steam ranges reasonably short, simple, and safe. Hence the advantages to be obtained by making the most of available space in connection with flues and draught plant are worthy of consideration for reasons other than and in addition to those associated with the ordinary economy of space in general. The fan plant, whose working has been referred to above, is illustrated in the sketches given in Figs. 2 and 3. On account of the lightness of structure, consisting

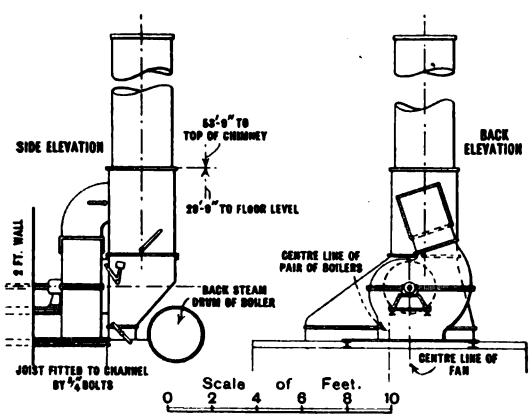

FIG. 2.—ARRANGEMENT OF FAN AND CHIMNEY. (CAPACITY : 45,000 CU. FT. PER MIN. AGAINST 2½ MINS. WATER PRESSURE.)

largely as it does of thin steel plates rivetted or bolted together, the plant is very conveniently placed so as to occupy no floor space at all, and this has proved to be an entirely suitable and thoroughly practical arrangement.

The passage from the final pass of the boiler rises vertically into the base of the chimney, so that when working on natural draught for light load, the full benefit of the chimney draught is obtained without any baffling at sharp bends and angles. Four dampers of the "butterfly" or "swing" type control the passage of the gases, so that either "fan" or "natural" draught can be put into service in a minute or two, for either or both boilers. The fan housing is carried on a half-inch steel plate bolted to two joists, which in turn are supported by the wall at one end and a steel channel, a member of the boiler framing, at the other end. The weight of the fan and motor is about 3 tons, and of the chimney, 4 ft. 6 in. diameter internally, of $\frac{3}{8}$ in. steel plate, is a little over 2½ tons; say 6 tons in all. The chimney top, 80 ft. above grate level, has a steel ring rivetted round, and to this four steel guy ropes are attached to stay the stack. The motor is carried on two steel joists embedded in the engine-room wall, in such a way that the weight of the fan is partially balanced against that of the motor on the remote side of the wall. The motor has the advantage of being in the cleaner atmosphere of the engine-room, and one of an open type

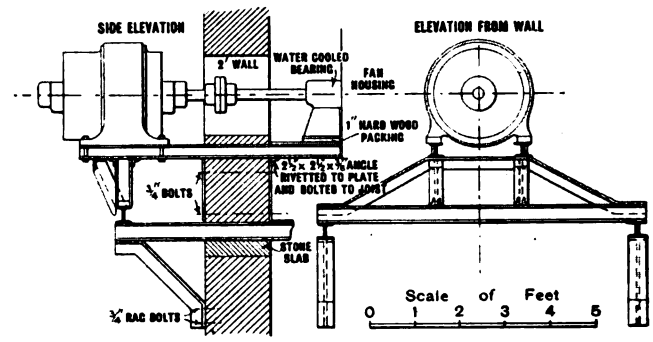

FIG. 3.—METHOD OF SUPPORT ADOPTED FOR THE FAN AND MOTOR AND FAN BEARING. (FAN MOTOR 35 B.H.P., 300/600 R.P.M.)

is used with its attendant advantages over the more or less enclosed type, which would be advisable in the presence of the more dusty atmosphere of the boiler-room. The tendency to vibration, liable to be set up when the fan runs at its higher speeds, is overcome satisfactorily by bracing the joists together, as shown in Fig. 3. Access for inspection is obtained by means of a light vertical wrought-iron ladder, attached to the wall, and a wood platform erected at a suitable height round the motor. The motor starter and speed regulator are placed at a convenient position for working from the engine-room floor.

The ground space occupied by a brick chimney of circular section is the area of a circle whose diameter is from one-twelfth to one-tenth of its height, as a rule, so that in the case of the example under present consideration, for a height of 186 ft. the external diameter at the base will not be less than 16 ft., and the area 201 sq. ft. The floor space occupied by the two boilers and stokers is 20·5 x 25 = 512·5 sq. ft., so that the chimney space is 39 per cent. of the boiler space. This ratio is reduced somewhat when a larger number of boilers is served by one chimney, but it is always a considerable proportion.

The weight of a brick chimney 186 ft. high, 6 ft. internal diameter, and 16 ft. external diameter at the base, is over 800 tons, exclusive of foundations, which would require to be very large and on good solid ground.

If the site were near a river, such as is frequently selected in order to obtain ample water supply, the ground would be liable to be of a marshy and unstable nature, necessitating an extensive system of piles to support the foundation.

A lighter structure is obtained if the chimney be built of steel, but the ground space occupied will be practically the same as with brick, for the lower portion must be well splayed out to give the necessary stability; and a firebrick lining is required for this as well as for the brick chimney. Reinforced concrete without any lining is in use in America for this purpose, but in this country there does not seem to be any example of this type of structure for chimneys, because, apparently, it is not definitely settled that the material will be reliable permanently, when subjected to temperatures of 800° F. and 900° F., for there is no doubt that cheap and light construction can be obtained by its use.

Unless the scheme is a very large one, it is the usual practice to erect only one natural draught chimney, in order to minimise capital expenditure, and one main flue, with by-pass if economisers are installed, consequently, the dimensions of the draught plant must be of sufficient magnitude to cope with such boiler extensions as are expected for some time to come.

For induced draught it is generally more suitable to install two, three, or more fans, each serving a boiler or group of boilers, and connected together through cross-flues so that any fan may do duty for any group of boilers. Fig. 4 shows the elevation and plan of a portion of the induced-draught plant at the generating station of the Sheffield Corporation tramways. Here the boilers and flues are divided into three sections, by two section dampers, which in the ordinary way are kept shut, so that each pair of boilers is served by its own fan or fans. This arrangement allows for the capital cost of the draught plant being incurred in proportion to the evaporative capacity of the boilers installed, contrary to the conditions which obtain with the natural draught chimney, and demand a considerable capital expenditure, whose full value is not made use of for perhaps some years.

The extreme reliability of a brick chimney is a very grea'

Digitized by Google

point in its favour, "there is nothing to go wrong. However, there are cases where cracks have developed in the brickwork and necessitated strengthening by clipping steel rings round the structure to prevent the fissures spreading and causing collapse. Further, with the important exception of loss of heat in the gases, the running costs are entirely contained in the charges for flue cleaning and pointing the brickwork at long intervals dependent on individual and local conditions. The reliability of a chimney is only to be equalled by installing two or more fans. As the fan is more reliable than the motor or engine which drives it, a considerable degree of reliability is obtained at less expense than by a complete duplicate plant, by arranging one fan so that it can be driven from either one of two sources of power, as, for example, in the generating station of the South Metropolitan Electric Light & Power Co., East Greenwich, where a large fan is direct-driven by a motor, which can be uncoupled if required, and the drive be taken by a steam engine, through chain gearing. In Fig. 4, No. 5 fan is driven directly by a high-speed steam engine, so that draught is obtainable when the main generating plant is not running. The other three fans are driven directly by variable-speed electric motors supplied by different mains from the station bus-bars.

Under working conditions when the demand for steam is variable, the natural draught chimney must be kept hotter than is necessary for the average demand, and the excess draught pressure is throttled by the main damper when the demand is slack. When the load comes on, the damper is opened wide to use the full temperature of the chimney to rouse the fires and obtain the more rapid fuel combustion now required. If a considerable "peak" load is anticipated, this must be done a few minutes in advance to obviate a temporary drop in steam pressure, which would otherwise follow. In fact, it is only on a fairly uniform steam demand that a natural draught chimney can be worked at the efficiency for which it is designed, and the more "peaks" the average demand has, the more will the chimney digress from its best efficiency on this account. Rapid variations of load taking place within two or three minutes, as a tramway traction load, will not have this effect so long as the mean load keeps fairly uniform. The boilers will have sufficient capacity to deal with the changes for so short a time, and the effect on the fuel consumption will be an average one, unaltered until the change is so great as to be beyond the water space capacity of the boilers between the limits of high and low water level.

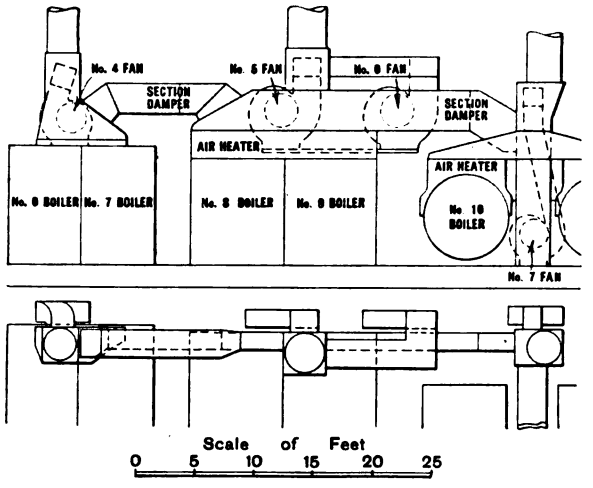

FIG. 4.—FANS AND FLUES.

With fan draught, coal combustion, and steam production in consequence, are under more instant control, the increased draught required to meet a sudden demand being obtainable at a moment's notice, by increasing the speed of the fan; and when the demand is unexpected, it is much more readily met than by the more gradual process of raising the temperature of the chimney gases. Similarly when the load declines rapidly, the fan can be more quickly and efficiently adjusted to the changed conditions, for the heat of the natural draught chimney must be allowed to waste in the process of cooling off.

The costs of the two systems can only be compared very roughly in general, but as they differ very materially in this respect, even an approximation will serve to indicate the contrasts between them, and show under what conditions each is likely to be at its best. Taking the case of fan plant and chimney (brick) of the dimensions previously used in this comparison, the approximate values of the different charges will be somewhat as follows in Table E:—

Table E.

Charges.	Natural draught chimney.		Induced draught plant.	
(*a*) Capital	say £1,000		say £300.	
(*b*) Interest and Sinking Fund	at 6%	£60	at 6%	£18
(*c*) Depreciation	at 2½%	£25	at 5%	£15
(*d*) Maintenance	at ½%	£5	at 1%	£3
(*e*) Power charges: ¼d. per kw. hr., 8·1 kw. for 365 days)	Nil		(i) 20 hrs. per day	£123
			(ii) 10 ,, ,,	£61·5
			(iii) 5 ,, ,,	£30·8
			(iv) 2½ ,, ,,	£15·4
Total annual cost...		£90	(i) 20 hrs. per day	£159
			(ii) 10 ,, ,,	£97·5
			(iii) 5 ,, ,,	£66·8
			(iv) 2½ ,, ,,	£51·4

In this particular example the total annual costs of the two systems are equal for an average daily service of about 9 hours; for longer service than this the chimney would be cheaper, for shorter service the fan would be so.

It is assumed so far that the chimney is worked with the same flue gas temperature as the fan is, *i.e.*, 439° F., but if the temperature were allowed to exceed this in the chimney by 35° F., making the temperature 474° F., then the extra loss in the gases, namely, 1·3 per cent. of the total furnace energy available, would cancel the power required to drive the fan, and the comparison of the costs would be made between the standing charges (*b*) and (*c*), resulting considerably in favour of the fan plant.

From the foregoing considerations it is to be concluded in general that if a natural draught chimney is to be as economical as an induced draught plant, it is essential that the temperature of the gases entering the former should be kept as low as in the latter, and then the load factor of the plant must be taken into consideration; a high value for this being favourable to the chimney and a low one to the fan. Table D shows that with a fan a very considerable increase above the normal draught pressure is obtainable when desired, up to 2·8 in. of water in the present instance. With the natural draught chimney of the given height, about 1·5 in. is the practical limit, and that with great loss of efficiency; as shown by curve C, the chimney temperature required would be about 750° F.

It is not economical to run a fan for long periods at a greater speed than that for which it is designed, because the power taken is increased in proportion to the cube of the speed when dealing with gas at a constant temperature, whereas the volume of gas discharged is only increased in proportion to the speed. With this limitation, the great draught capacity attainable by a fan is of use at times when shortness of boiler power has to be met, and by its help coal consumption may be increased to 30 or 40 per cent. above the normal rate, and evaporation in nearly the same proportion. If coal consumption is forced beyond 35 or 40 lbs. per sq. ft. of grate area with mechanical stokers, there is considerable risk of parts of the mechanism being damaged by over heating, the back ends of moving bars and the surfaces of chain gates, and air seals of the latter, if metallic, being the principal parts to suffer. However, the draught required to produce this rate of combustion with any but the best coal is usually 2 in. or over, and the most efficient evaporative results are obtained below this limit, so that it is very exceptional that risk need be incurred in this direction.

Further, this property of the fan makes its application very suitable for burning cheap small fuels which generally require strong draught, over one inch water pressure for combustion, to take place rapidly enough to make good use of the grate area. The question of advantages connected with the burning of cheap fuels was thoroughly gone into in two Papers read before this Institution on November 23rd, 1899, namely, "The Cost of Steam Raising," by John Holliday, and "Influence of Cheap Fuels on the Cost of Electrical Energy," by R. E. Crompton. Curves A_1, A_2, show that for burning this class of fuel, chimneys of less than 180 ft. high must be very inefficient compared to a suitable induced draught plant.

It is frequently quoted that with mechanical draught a smaller excess supply of air than that demanded by theory, is required, than with natural draught. In all probability this arises from the fact that natural draught pressures are as a rule considerably lower than those mechanically produced, and fires are worked with less thickness with the former, so that such a thorough and uniform mixing of the coal and air does not take place, as with the greater pressure and thicker fires of the latter. But if the conditions are equal in respect of draught pressure

Digitized by Google

and thickness of fires there is no reason that a larger air supply is required with one system than with the other

It is of more importance that attention be given to the regulation of a fan when load is going off than to a natural draught system in the same case, because the latter is to a considerable degree automatic, the former is not. At such a time, in any case, the coal feed is slackened off, and even if the damper regulation with natural draught is neglected the resultant flue gases are cooler and reduce the draught pressure so that the proper value is attained eventually, though less rapidly and efficiently than if the damper were regulated to assist. In the same circumstances a fan left running at too high a speed for the lighter load, with the coal feed reduced, causes the back portion of the grate to burn bare, with the exception of the thin covering of clinker and ash, through which excess cold air is admitted and the steam generation is reduced by loss of furnace efficiency. Meanwhile the power taken by the fan remains the same as when more evaporation was taking place, so that a double loss is being incurred. Hence it is essential for the economical working of a fan plant on a varying load that both the draught and coal feed be adjusted to suit the demand, and the limiting conditions are, on the one side, that the coal shall not be completely burnt before it reaches within a few inches of the back of the grate, and on the other side that no unconsumed fuel shall fall into the ashpit. The corresponding adjustments for a rising load with either system of draught, if not promptly attended to, draw attention to themselves in an immediate and insistent manner by a falling off in steam pressure.

For reducing the temperature of gases leaving the boiler the Ellis and Eaves air-heating system for supplying the furnaces with hot air is one which is frequently used in conjunction with induced draught plant. The air supply is heated either inside long horizontal tubes round which the flue gases pass, or outside shorter vertical tubes with the flue gases conducted inside. In the latter arrangement the close contact required between the tubes and the air to be heated is obtained by fixing over the tubes near the air inlet a diaphragm plate with holes about ½ in. larger than the outside diameter of the tubes, which are centrally disposed in the holes so that the air enters the annular openings adjacent to the tube surfaces and is effectively heated. Suitable vertical baffle plates are also fitted to obtain a good distribution of air over the heating surface. As an example of the kind of result obtainable with short vertical type air-heaters the three following sets of figures are extracted from tests on a 10 ft. by 10 ft. double furnace marine boiler thus equipped, and with no other heater or economiser in the flues, so the value of the air-heater may be estimated when it is understood that the temperature of the flue gases in the smoke-boxes, upon the top of which the air-heaters were fitted, is usually over 600° F.

Method of firing.	Draught pressure.	Coal consumed per sq. ft. grate area.	Temperature of flue gases leaving air-heater.
Hand	2 ins. (approx.)	30·5	404° F.
Hand	,, ,,	33·1	335° F.
Mechanical ...	,, ,,	40·5	499° F.

Briefly, the advantages of induced draught are :—

(1) Greater efficiency obtainable, by lower temperature of flue gases.

(2) More suitable for burning cheap fuel on account of greater draught pressure obtainable.

(3) Coal combustion can be largely increased at times of emergency, allowing less spare plant to be installed.

(4) Greater facility and efficiency in suiting draught to variations of load.

THE QUARTZ MERCURY VAPOUR LAMP

SOME particulars of the quartz mercury-vapour lamp were published in ELECTRICAL ENGINEERING, Vol. II., p. 549. We are now able to give some further details as to the actual construction. The quartz lamp is a mercury-vapour lamp in which the arc is surrounded by a transparent quartz tube from 3 to 6 in. in length. At the ends of the tube quartz receptacles are placed which contain the mercury electrodes. These receptacles are surrounded by fan-shaped coolers of copper, by means of which the heat radiation and the value of the current are regulated. The burner is attached to a metal plate, *A*, which carries a reflector placed above the light tube. By means of the pivots placed at the end of the metal plate the burner is attached to the supports provided in the lower part of the lamp casing, so that it can turn. An operating rod, *U*, which is suspended from the upper part of the lamp, is allowed to hang down through the loop *Y* attached to the metal plate. A shunt-wound magnet, *Q*, is placed in the centre part of the lamp casing, and the previously-mentioned operating rod, *U*, is attached to the armature arm of this magnet. On the plate above the electro-magnet, *Q*, a cylindrical choking coil, *L*, is placed, surrounded by a rheotan resistance, *M*. Around this latter six iron resistances, *H*, enclosed in air-tight glass cylinders, are fixed, these resistances being connected in parallel with one another, but in series with the rheotan resistance, the choking coil and the burner, whereas the shunt-wound magnet, *Q*, is connected in parallel with the burner. The choking coil *L* serves to prevent the lamp from being extinguished should the voltage fall suddenly. At its lower end it carries an iron piece, *N*, projecting sideways, which is placed opposite to a small movable iron piece, *O*. This iron piece lies in the circuit of the shunt-wound magnet, *Q*, and breaks the same at *P* as soon as it is drawn up from the iron piece, *N*, by the choking coil. When the lamp is switched in, no current passes through the burner itself, owing to the fact that there is no connection between the mercury electrodes, the current passing instead through the electro-magnet, *Q*, connected in parallel with it. This latter draws up the armature, *R*, and, by means of the operating rod, *U*, tilts the burner on its axis, so that the mercury can flow from the positive to the negative electrode receptacle. The current now set up magnetises the choking coil, *L*, which immediately attracts the iron piece, *O*, and consequently interrupts the circuit of the shunt-wound magnet, *Q*. The latter, therefore, releases its armature, *R*, the burner returns again to its former position of rest, and an arc is now formed in the light tube as the mercury flows back from the negative to the positive receptacle. Shortly after ignition, the burner only absorbs approximately 30 volts, and, therefore, gives very little light. Its full voltage (85/90 volts for 110-volt lamps, 165/185 volts for 220-volt lamps) is first attained when the electrode receptacles are thoroughly warmed, and the full brilliancy is reached at the same time. The warming of the electrode receptacles and the increase in brilliancy will take place more rapidly the higher the current is, as the latter will flow through the burner from the beginning. On this account iron resistances are connected in series with the burner, and are enclosed in air-tight glass covers in order to allow a high current to flow through them as long as the burner voltage remains low. During this period these resistance glass covers will become noticeably hot, should any resistance fail to exhibit this feature or remain cold after the lamp has been switched in, this is a sign that it is burnt out, and must be replaced; if this is not done the starting current will be too low, and a considerable time will elapse before the burner is sufficiently warm; it will also take a very long time for the latter to reach its full brilliancy, or it may entirely fail to do so. Only the lamps for 3·5 amps. 220 volts and 4 amps. 120 volts are provided with iron resistances; for the 2·5 amps. 220-volt lamp they are not necessary.

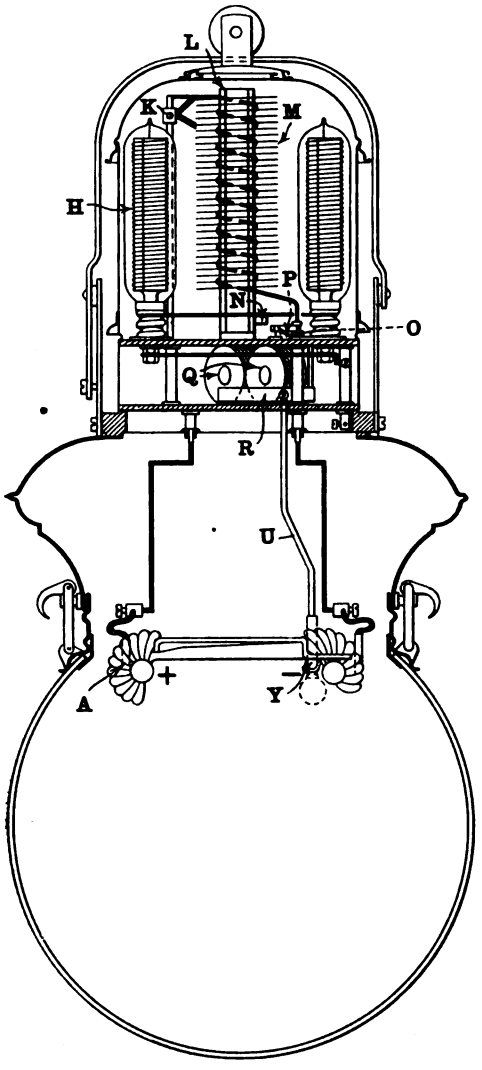
The rheotan resistance, *M*, is provided with a sliding contact, *K*; if this is moved upwards, the resistance is increased and the burner voltage will be reduced. The lamps may, therefore, be used without further alteration for high pressures (up to 220 volts for 120-volt lamps), if the sliding contact of the rheotan resistance is moved to its highest point. In installations in which large voltage variations take place, all resistances must be placed in series, that is to say, the sliding contact must be moved to its highest point, otherwise the lamps may be extinguished if the voltage falls suddenly. The current in the lamp is dependent solely upon the cooling of the electrode receptacles: it rises if the lamp is allowed to burn without a globe, or if globes or burners which are intended for indoor use are used in the open air, on account of the fact that the metal cooler will be surrounded by colder air. Higher currents, however, bring with them the danger of the softening of the quartz tube; for this reason the lamps should never be allowed to burn without globes or with broken globes. Burners required for use without globes for special purposes must be specially constructed.

When connecting up the lamps care must be taken that the correct polarity is observed. A strong flickering of the light which does not entirely disappear a few minutes after the lamp has been switched in, is usually a sign that the latter is burning with the current reversed, or that the burner has not entirely returned to its original position of rest, and, therefore,

Digitized by Google

the electrode receptacles are not lying in a horizontal position. The light tube of the burner should not be touched with the fingers, as the moisture of the skin attacks quartz as soon as it is warm. It then plainly shows the impressions of the fingers, which cannot be removed. Should the light tube be accidentally touched with the fingers, it must be cleaned with a rag dipped in alcohol or spirit.

The light given by the quartz lamp is exceedingly rich in the ultra-violet rays, which will cause inflammation of the skin, and particularly in the eyes, even if only exposed for a few seconds; their influence, however, makes itself first felt after several hours through intense pain in the eyes, and by a noticeable reddening of the skin. Spectacles are not sufficient to



SECTION OF QUARTZ MERCURY-VAPOUR LAMP.

protect the eyes unless they have side glasses to prevent the entrance of the rays. On this account quartz lamps should never be allowed to burn without glass globes which entirely absorb the ultra-violet rays. These rays possess insect-killing properties, and are found to destroy all flies, moths, mosquitos, &c., coming within their range. When used for the above purpose, however, the lamps are supplied with a different form of globe. The colour of the light emitted is rather less bluish than the light of the ordinary mercury-vapour lamp, but is nevertheless far from pleasant. The lamp is manufactured by the Allgemeine Elektricitäts Gesellschaft, of Berlin, and further particulars can be obtained from their London representatives, the Electrical Co., Ltd. The lamp is, however, not yet on the London market, but we understand that it is supplied by the A.E.G. Co., of South Africa, for the Colonial market.

Electrical Football League.—The following matches take place next Saturday in the above League:—Metropolitan Electric v. St. James' Electric, at Willesden; Ediswan v. General Electric Co., at Wormholt Farm (No. 8 pitch); St. Pancras Electric v. County of London E., at Swain's Lane, Highgate. The kick-off is at 2.45 in each case.

CATALOGUES AND PAMPHLETS RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering"].

ARC LAMPS.—A carefully arranged and well illustrated catalogue is to hand from the Electric & Ordnance Accessories Co., Ltd., of Cheston Road, Aston, Birmingham, in which the various patterns of arc lamps manufactured by this firm are described. Ordinary and inverted enclosed lamps, miniature lamps for indoor and outdoor use, flame-arc lamps, and accessories of all kinds are listed. A useful feature of the catalogue is the series of instructions for fixing and running the various patterns of lamps, all of which are illustrated with diagrammatic sketches showing the connections necessary. The mechanism of the lamps is also described and illustrated. Among the accessories is the new "Victor" clutch, a description of which was given in our second Manchester Exhibition Supplement.

BRUSHES.—Messrs. J. & H. Grevener, of Eldon Street House, London, E.C., have issued a new price list of metal and carbon dynamo and motor brushes. It contains a large range of sizes and detailed directions both for ordering the brushes and for using them.

COAL CRUSHERS.—A pamphlet from the Pennsylvania Crusher Co., of Philadelphia, U.S.A., describes a number of patterns of hammer crushers and coal cleaners for crushing and sorting coal for coking ovens. Magnetic separators and rotary crushers are also described.

ELECTRICAL SUPPLIES.—A stiff board cover has just been issued by the British Westinghouse Electric and Manufacturing Co., Ltd., of Trafford Park, Manchester, in which are filed over forty leaflets, dealing with electrical apparatus and accessories of all kinds. Most of these leaflets have been issued during the present year, and therefore the catalogue is quite up-to-date. A classified list of apparatus and an index to the catalogue numbers is provided for convenience in ordering. The most recent additions are leaflets dealing with the Westinghouse-Bremer flame-arc lamps and accessories, and continuous and alternating-current enclosed arc lamps. The other lists have been mentioned in our columns from time to time, and concern metal filament lamps, fittings, small motors and controlling gear, switchgear, heating apparatus, transformers, instruments, telephones, and various other electrical supplies and accessories.

ELECTRIC HEATERS.—A neat little card is to hand from the Electric & Ordnance Accessories Co., Ltd., of Cheston Road, Aston, Birmingham, on which are illustrated six patterns of electric heaters, including two glow-lamp radiators. One of the latter has a metal network screen to protect the lamps. Consumption and prices of the various patterns are given on the card.

MOTOR-CAR ACCESSORIES.—A new catalogue of motor-car accessories has just been published by Messrs. Siemens Brothers & Co., Ltd. The first half of this catalogue deals with ignition apparatus, including low-tension magnetos, ignition coils, with a new patent interrupter, sparking plugs, accumulators, and the Siemens-Obach dry cells. Pocket ammeters and voltmeters, pole indicators, and a "capacimeter," which is really a low-resistance voltmeter for indicating the terminal voltage of the battery under working conditions, are also listed. Among the items included in the second half are charging sets, speed indicators on the voltmeter principle, electric horns, switches, hand lamps, motor-car lamps, communicators for indicating to the driver the desired speed or other information, and, lastly, low- and high-tension leads for the ignition circuits. Messrs. Siemens Brothers & Co. showed examples of nearly all the above at the recent Motor Exhibition at Olympia

SINGLE-PHASE MOTORS.—Two card leaflets from the British department of the Maschinenfabrik Oerlikon, Oswald-estre House, Norfolk Street, Strand, give particulars and prices of squirrel-cage and slip-ring single-phase motors respectively. The first-named are built for outputs ranging from $\frac{1}{3}$ to 5 h.p., and the slip-ring motors for outputs up to 50 h.p. The figures refer to 50-cycle motors for any pressures up to 250 volts. Complete particulars as to weights are given, and information relating to the necessary accessories is also included.

TELEPHONE APPARATUS.—A pamphlet is to hand from the British Insulated and Helsby Cables, Ltd., of Prescot, Lancashire, in which a new piece of apparatus, termed the "Phantophone," and permitting the application of telephones to existing telegraph and signalling circuits of relatively short length, is described. The instrument is made in three distinct patterns to suit the following three typical sets of conditions:—(*a*) The connection of a telephone circuit to a single line telegraph or block signalling circuit; (*b*) The connection of a telephone circuit across two single wire telegraph or block signalling circuits, each of the latter being worked independently, while the telephone circuit forms a metallic loop; (*c*) the connection of an earthed telegraph circuit to a metallic loop telephone circuit. In the first case the phantophone is joined directly to the line at each end, and an impedance coil is connected in the line circuit at each end to reduce the tendency to interference with the phantophone. In the third case, the telegraph current is

Digitized by Google

divided at each end through a differential impedance coil, which is so wound that it is ineffective inductively to the telegraph currents, but offers great impedance to the telephone currents. Further particulars and prices of the above instruments and accessories are given in the pamphlet. Another pamphlet from the same firm relates to self-sealing condensers for telegraph and telephone circuits, made under the Mansbridge Patents. The stock sizes have capacities ranging between 0·05 and 3 microfarads; the approximate weight of the largest, namely, 3 microfarad capacity, is 14 oz.

WIRING ACCESSORIES.—We have received from Messrs. Johnson & Phillips, Ltd., a leaflet describing various patterns of cut-out boards, switches, lamp-holders, wall-plugs, ceiling-roses, and other fittings. Each article is well illustrated, so that its chief features can be seen, and full particulars and prices are given. Messrs. Johnson & Phillips ask us to state that they will send this list to anyone interested who applies to them, mentioning ELECTRICAL ENGINEERING. Another leaflet from the same firm relates to searchlight projectors of different sizes, taking from 10 to 80 amperes continuous current.

LONDON ELECTRIC POWER BILLS

London and District Bill Rejected.

At the conclusion of Mr. J. D. Fitzgerald's speech in reply to the opposition to the London and District Electricity Supply Bill on Wednesday last week, the Chairman, after a brief adjournment, announced that the Committee were unanimously of the opinion that the preamble of the Bill was not proved.

London Electric Supply Bill.

The consideration of this Bill was commenced on Thursday morning. Mr. Balfour Browne, K.C., who appeared with Mr. C. C. Hutchinson and Mr. Tyldesley Jones for the eight companies, stated the objects of the Bill, which are to give authority for linking up the power stations and undertakings of the promoting companies, and to authorise the supply of electrical energy to railways, tramways, canals, docks, &c., even if such energy is not to be used within the area of either of the companies in question. The companies concerned in the promotion are Charing Cross, West-End & City Electricity Supply Co., Metropolitan Electric Supply Co., London Electric Supply Corporation, Chelsea Electricity Supply Co., Brompton & Kensington Electricity Supply Co., South Metropolitan Electric Light & Power Co., London Electric Lighting Co., and the County of London Electric Supply Co.

Evidence in support of the preamble was given by Mr. J. B. Braithwaite, Chairman of the County of London Electric Supply Co.; Mr. C. P. Sparks, engineer to the company; and Mr. J. S. Highfield, the engineer to the Metropolitan Electric Supply Co. There was very little opposition on the preamble of the Bill, but a heated discussion took place at a later period in connection with the various instructions from the House of Commons with regard to the insertion of certain provisions in the Bill, which were not proposed by the promoters. So rapidly was the preamble disposed of that the representatives of the City Corporation and the Westminster City Council were quite taken aback when the Chairman announced that the preamble was found proved. Mr. Rigg, K.C. for the former, and Mr. Blennerhassett, K.C. for the latter, immediately asked to be allowed to give evidence against the preamble, but, having given his decision, the Chairman refused. The special case of Southwark, however, had previously been heard. In Southwark, as has been pointed out very many times during these proceedings, there are two companies and a local authority in competition, and the Borough Council is fearful lest the two companies should link up their two systems, and thus, instead of there being competition between the two companies as well as the Council, there would be competition only between one much stronger company and the Council, to the detriment of the latter. Mr. Vesey Knox, K.C., for the Southwark Borough Council, had asked that in the event of any agreement between the two companies for a supply, the Borough Council should be brought into that agreement and given the option of taking a supply in bulk from the company's undertaking upon the same terms. He also asked that a provision should be inserted in the Bill preventing anything more than the distribution mains of one of the competing companies being taken over by the other, in the process of consolidation which is anticipated in the Bill. His arguments, however, had no effect upon the Committee, and, as stated above, the preamble was found proved.

The Committee then went into the consideration of the clauses, first of all in relation to the instructions from the House of Commons. It will be remembered that one instruction was to the effect that purchase powers on the part of the London County Council should be inserted in the Bill, and another that linking-up powers should be conferred upon the local authorities of London under the Bill.

Mr. G. M. FREEMAN, K.C., for the London County Council, stated that he entirely supported the instruction, he understanding it to mean that the London County Council should be substituted as the purchasing authority for the local authorities, and should be able to purchase all the companies' undertakings in 1931 upon equitable terms. During a very long discussion upon this instruction, it was made clear that the London County Council will have no powers of purchase over the Borough Councils' electricity undertakings, and that operations with regard to the companies will be entirely confined to the county of London.

The special cases of the City of London and the Camberwell Borough Council were the cause of considerable discussion, which almost at one time resulted in the promoters withdrawing the Bill. The City of London Corporation has powers to purchase portions of the undertakings of the City of London Electric Lighting Co. and the Charing Cross, West End & City Electricity Supply Co. before 1931, and strong objection was taken to being deprived of these powers. The same point was argued on behalf of the Camberwell Borough Council, which has powers to purchase that portion of the County of London Electric Supply Co.'s undertaking relating to Camberwell at any time upon the payment of £133 for every £100 of capital expenditure in respect of the supply to Camberwell. The Committee, after hearing the arguments, decided that any rights of local authorities to purchase before 1931 must not be interfered with. This did not quite satisfy Mr. Balfour Browne, for the promoters of the Bill. He wanted the position to be created that no purchase could take place with regard to any of the companies until 1931, and then only by the London County Council. The Committee, however, adhered to the decision mentioned above, viz., that no rights of purchase before 1931 shall be interfered with, adding that if in 1931 such local authorities have not exercised their rights of purchase, then the London County Council shall do so in common with the rest of the companies' undertakings.

The Westminster City Council, represented by Mr. Blennerhassett, entered a most emphatic protest against the Chairman interpreting the instruction of the House as a mandatory instruction. Counsel argued that it was purely a permissive instruction, and that to insert it in the Bill would be to negative the whole object of unification of electric supply in London, inasmuch as there was no power for the County Council to buy up the local authorities. The Chairman interrupted that the County Council could purchase the local authorities' undertakings by agreement. Mr. Blennerhassett, however, continued his argument, and stated that to take away the valuable rights which the borough councils now have of purchasing in 1931 was nothing more than confiscation and robbery; it was the most unheard-of thing to introduce such powers in a comparatively small and unimportant private Bill. The Committee by doing so would be altering the public general law of the country, and there was no doubt in his mind that the instruction did not impose upon the committee the responsibility of taking this tremendous step. The London County Council had never asked for the right to purchase, and to transfer these powers without compensating all the borough councils was monstrous. It may be pointed out, however, that with the exception of Westminster, the City Corporation, and Camberwell, there was no opposition on the part of the borough councils to the London County Council being constituted the purchasing authority in their stead. In fact, the two latter do not oppose the County Council purchasing in 1931, and impression was rather given that the borough councils generally will be only too pleased to be relieved of their powers in this respect. A further special case arises in Southwark, however, in which the possibility of the London County Council, in possession of the two companies' undertakings, would be competing with the borough councils' undertaking. This was pointed out to the Committee, and Mr. Vesey Knox suggested, as a way out of this anomalous position, that when the County Council purchases the two companies who now supply in Southwark, they should also purchase the undertaking of the Southwark Borough Council. In spite of all these arguments, however, the Chairman insisted upon a literal interpretation of the instruction, and inserted in the Bill the bare statement that the London County Council shall be entitled to purchase the electric supply company of London in 1931 upon equitable terms.

When the Committee met on Friday, Mr. Balfour Browne, for the companies, put it to the Committee that the decision of the previous day, that the existing special rights of purchase in the case of the City of London Corporation and the Camberwell Borough Council should not be interfered with, created a serious difficulty. It is the avowed desire of the companies, under the new purchase conditions, to have all their undertakings pur-

Digitized by Google

chased in 1931 by the London County Council, thus enabling them to be consolidated into one undertaking. If the special rights of the City and Camberwell were preserved, it was argued that consolidation would be impossible, if they were to purchase their respective undertakings prior to 1931. Mr. Balfour Browne therefore asked the Committee to say that the existing rights in these two special cases should be nullified. This proposition was at once most strenuously opposed both by the City Corporation and the Camberwell Council, represented by Mr. Rigg, K.C., and Mr. Talbot, K.C., both of whom suggested that there was an ulterior motive in this proposal. After a long argument and discussion, the Chairman announced that the Committee was unanimously of the opinion that their decision of the previous day, viz., that any rights of local authorities before 1931 should not be interfered with, must stand.

Mr. BALFOUR BROWNE immediately asked for an adjournment, hinting at the possibility of withdrawing the Bill. Upon this, Mr. H. Lloyd, K.C., asked, on behalf of Marylebone and some other Councils, that such a course of procedure should not be allowed by the Committee; if the present promoters did not wish to proceed, his councils desired to take up the Bill themselves.

The CHAIRMAN, who had Mr. E. Moon, K.C., Speaker's counsel, by his side, queried whether the Bill could be withdrawn, and Mr. Balfour Browne replied that the promoters would consider this also. Consequently it was agreed at 12.30 to adjourn until 2 p.m.

When the Committee met again at 2 o'clock on Friday, Mr. Balfour Browne stated that he had looked up the authorities on the subject of withdrawing the Bill, and after quoting from the standing orders and from the proceedings of the House itself in similar circumstances, said he thought it was quite clear that it would have been competent for him to withdraw the Bill. The Chairman pointed out that there were precedents the other way, and there had been a case in which the opponents of the Bill had been allowed to take it up after the promoters had withdrawn it. One such case, he said, had happened in 1828! Mr. Balfour Browne's reply was that just as many things might happen before 1931, so many things had happened since 1828. Continuing, however, he said he had considered the matter, and although he did not really know the full effect of the decision upon the Bill at the moment, he was not prepared to advise his clients to withdraw the Bill, having regard to the importance of some of its provisions from a public point of view. At the same time, in deciding this, he wished to keep faith with the arrangement made with the Board of Trade, viz., that if the purchase clause did not meet with his approval, he was to have the right to withdraw the Bill. In support of his argument that the special powers of the City and Camberwell should be repealed, he produced a report which had just been issued by the Board of Trade upon the Bills, in which it was stated that the special powers were of comparatively little value, and that it was quite within the Committee's power to repeal them. He wished he had known of this before the adjournment, as he felt that it would have strengthened his case very much. The Chairman interrupted that, as a matter of fact, he knew of the existence of this report before Mr. Balfour Browne's speech, and that the Committee had not seen their way to influence their decision in consequence of it.

Mr. Balfour Browne then brought up a clause stipulating under what conditions the London County Council may purchase. This provided that the County Council should give ten years' notice of its intention to exercise its powers of purchase and that all the companies were to be purchased, and not only some of them. The clause carried out the ruling of the Chairman with regard to the preservation of any existing rights of purchase before 1931, and further laid down that the purchase price for the undertakings acquired by the County Council should not be worse terms than those of Section 2 of the Electric Lighting Act of 1881, which are the minimum which the companies can now obtain. If purchase does not take place in 1931, then the County Council may exercise its powers at every subsequent period of ten years. A further clause provided for the borrowing of money by the companies from the London County Council after the notice to purchase has been given, owing to the difficulty which it is felt the companies will experience in raising capital for any new works that may be required during the latter portion of their existence. The money so loaned by the County Council, however, upon which the companies propose to pay interest at the rate of 3½ per cent., would be deducted from the purchase price paid for the undertakings as a whole. One other proposal was made in this connection, consequent upon a remark by the Chairman, namely, that if the City Corporation and the Camberwell Borough Council do not purchase the undertakings over which they have the rights at the specified times in their agreements, a limiting period of ten years should be inserted in the Bill within which these rights should be exercised, otherwise they should cease.

At the close of the reading of these clauses, Mr. Freeman, for the London County Council, asked for an adjournment in order that they might consider them. So far as he had heard them, he said, they seemed to him to be a "monument of misplaced impudence."

This request for an adjournment, which was eventually agreed to by the Committee, was followed up by an application on behalf of the Lambeth Borough Council that its special powers of purchase should be preserved in the clause, in the same way as those of the City and Camberwell.

The discussion upon these clauses having been adjourned until the following Tuesday, Mr. J. D. Fitzgerald, on behalf of the Metropolitan Water Board, proposed a clause providing that in respect of the new mains to be laid under the Bill for linking up the various power stations of the companies, special protection should be given to the mains of the Water Board. He asked that, instead of three days' notice allowed under the general law, seven days should be given; that a plan of proposed works should be handed by the companies to the Water Board; and that no work should be carried out nearer to a water main than 6 ft. without notice being given to the Water Board. Some evidence upon this matter was given in which it was shown that water mains were frequently interfered with by electric lighting and other companies without the knowledge of the Water Board, causing serious inconvenience and loss. The clause was eventually granted, in spite of the very strong opposition of the promoters.

The Chairman further stated, in announcing the adjournment until Tuesday, that a clause was to be inserted in the Bill granting the Borough Councils power to link up in the same way as those given to the companies.

On Tuesday, at the commencement of proceedings, sympathetic reference was made by the Chairman to the death of Sir Ralph Littler, K.C., who has been appearing before the Committee from the commencement as leading counsel for the City Corporation. Sir Ralph, it may be pointed out, was also leader of the Parliamentary Bar. The Chairman was supported by Mr. Balfour Browne, K.C., on behalf of the Parliamentary Bar, and Mr. H. L. Cripps, on behalf of the Society of Parliamentary Agents.

The consideration of the clauses placed before the Committee on Friday, with regard to the purchase of the companies' undertakings by the London County Council, was then continued. Mr. J. B. Braithwaite, chairman of the County of London Electric Supply Co., was called by the promoters, and expressed the opinion that the companies should be granted compensation, above the terms of the Electric Lighting Act of 1888, by reason of agreeing to the L.C.C. as the purchasing authority, inasmuch as in so doing they gave up their right to compensation for severance, in the interests of consolidation. He attached considerable importance to the words "equitable terms" in the instruction, and without these the companies would not have proceeded with the Bill in the face of the instruction. It appears that the instruction on this point was brought forward by the Board of Trade by agreement with the companies, who hope to get something more than the terms of the Electric Lighting Acts under the words "equitable value," in view of the question of severance. Further, it is stated that the companies understood the instruction to mean that any rights of purchase before 1931 should be extinguished. Mr. Braithwaite went so far as to say that the companies may yet withdraw the Bill on this account. Mr. Freeman, who cross-examined Mr. Braithwaite on behalf of the London County Council, soon showed a very considerable difference of opinion between the Council and the companies. The Council wishes Electric Lighting Act terms, without any additions whatever; they oppose the lending of money during the term of notice, and also the giving of ten years' notice. Further, they do not wish to be compelled to purchase the Willesden station of the Metropolitan Electric Supply Co., which is the case under the proposed clause. The further the instruction to the Committee is considered, the more ambiguous does it become, for it seems that the companies, the Committee, and the London County Council are interpreting it in a different way, and the proceedings as a whole rather give the impression that the Bill is one for altering and amending the Electric Lighting Acts.

Whilst the County Council case with regard to the cumulative effect of the companies clause was being placed before the Committee, the Chairman said the Committee was in favour of some notice being given, but not to anything like the extent mentioned, viz., ten years. Also the rate of interest to be paid upon any money lent by the Council should be left to the Board of Trade.

During further discussion upon the clause proposed by the company, and a counter-clause of the L.C.C. outlined above, the L.C.C. agreed that the arbitrator in 1931 should have power to add a sum for the additional value of the companies' undertakings by reason of linking up. In support of the companies' claim for severance, Mr. Balfour Browne pointed out that, even with the L.C.C. as purchasing authority, there must be severance if the powers of purchase before 1931 are exercised. Portions of various undertakings are purchasable in 1927, 1928, 1941, and 1914, and if these powers are exercised by the local authorities as they can be under the Bill, then there must be severance.

During the discussion Mr. Freeman, for the L.C.C., agreed to a condition that money might be lent to the companies during the period of notice, but he objected to an obligation.

Subsequently the Committee passed the scheme of Mr. Balfour Browne's clause, with the alteration of the period of notice

Digitized by Google

from ten years to three years. Some of the Committee, as a matter of fact, were in favour of two years' notice. Some drafting amendments were then made in the clause to provide for certain special purchase terms given to the Charing Cross Co. under their order being preserved. The Committee also decided that the County Council should not be compelled to purchase the Willesden station of the Metropolitan Electric Supply Co., it being understood that the company will have to be paid compensation for severance. A request by the City Council of Westminster that the powers of purchase of the L.C.C. over the companies supplying in their district should be suspended until the next Bill is heard was refused.

Yesterday the Committee decided that the L.C.C. should be compelled to lend money to the companies during the three years prior to purchase. It was also decided that the payment to the companies, when they are purchased, should be half in cash and half in stock.

A new clause was proposed by the L.C.C. for inserting in the Bill a maximum charge for power consumers of £6 15s. per kw. of maximum demand per annum, plus 0·33d. per unit, but after discussion it was decided to leave the exact figure for a conference of all the company and municipal electrical engineers in London in order to arrive at an equitable figure.

THE PARLIAMENTARY SESSION OF 1909

PARTICULARS are now available of some of the Bills which will be deposited in Parliament for the session of next year.

The Central London Railway Co. proposes to extend its line to Liverpool Street, commencing by a junction with the existing railway of the company at the Bank and carrying it under Old Broad Street to a point under the Great Eastern Railway near Bishopsgate Street Without.

The North-East London Railway Co. will seek an extension of time granted by its Acts of 1906, 1907, and 1908, which prescribe the period in which a portion of the capital of the company shall be subscribed. The Bill will also include an application for the extension of the time within which a substantial commencement of the works has to be made.

A Bill promoted by the London United Tramways Co. will provide for the maintenance of through routes, bookings, and fares between the company's tramways and other tramways and railways, and will also seek to alter, vary, or repeal the provisions of the Acts, &c., under which the company may be required to sell the portions of its undertaking in Hammersmith to the London County Council. The Bill also provides for running powers over certain of the London County Council lines, with reciprocal running powers on the part of the Council over some of the company's lines. An extension of time is also sought for the compulsory purchase of lands under the company's Act of 1907, and in connection with the construction of the tramways authorised by the Act of 1904.

The West Kent Electric Co., Ltd., will seek to transfer to itself certain powers now vested in the Kent Electric Power Co. conferred by the Bromley Rural District Electric Lighting Order, 1903, together with certain alterations and amendments of the provisions of that order as to compulsory works and purchase, to authorise agreements for supply in bulk, &c.

An extension of time for the purchase of lands and property, &c., and for the completion of works under its Act of 1906 will be sought by the Baker Street and Waterloo Railway Co. Powers will also be sought for the payment of interest out of capital during construction, for the acquisition of additional land for extending station premises at Oxford Circus, the abandonment of certain subways authorised in 1905, &c.

The National Electric Construction Co. are seeking powers to construct the Folkestone, Sandgate, and Hythe tramways upon the overhead trolley system instead of upon the surface-contact system as stipulated; another Bill seeks to vary the terms of the agreement with the Oxford Corporation for the provision of electric tramways.

A Bill will also be deposited for the incorporation of the City of Bath Electric Supply Co., to which the municipal electric supply undertaking of Bath is to be transferred.

Electric Lighting Provisional Orders will be applied for by the Macclesfield Electric Light & Power Co., the Hindhead & District Electric Light Co., Turton Urban District Council, Herne Bay Urban District Council, Cleethorpes Urban District Council, Yorktown & Blackwater Gas Co. (Camberley), Chesham Electric Light & Power Co., Staines Electric Light Syndicate.

The Oldham Corporation will seek powers to construct some additional tramways and use the trackless trolley system, as also will the Liverpool Corporation, Bradford Corporation, Manchester Corporation, and Salford Corporation. The latter also seek powers to supply electricity in adjoining areas. Additional tramways are also sought to be constructed by the Whitworth Urban District Council, Torquay Tramways Co., London County Council, and Gateshead & District Tramways Co.

The Light Railway Commissioners will seek powers to revive the County of Middlesex Light Railway Orders of 1901, 1903, and 1906, in respect of the compulsory purchase of lands.

In a General Powers Bills, the Bradford Corporation and the Cardiff Corporation seek to supply electrical energy in bulk in adjoining areas.

An application will be made to the Light Railway Commissioners for the construction of a light electric railway between Rhyl and Prestatyn.

The reorganisation, rearrangement, and increase of its capital, will be sought in a Bill by the Anglo-Argentine Tramways Co., and the confirmation of an agreement between the British Electric Traction Co. and the Dudley Corporation is proposed in a Bill by the latter. A consolidation Bill by the Bury Corporation deals with all the Corporation's trading undertakings.

The North Metropolitan Electric Power Supply Co. seek an extension of their powers in Hendon, Finchley, Friern Barnet, Hornsey, Walthamstow, Chingford, and Waltham Holy Cross for the supply and distribution of electrical energy; also to supply for traction purposes.

The County of Durham Electric Power Co. seeks the legalisation of agreements between the various Tyneside power companies, &c.

A Bill will be promoted for the revival of the compulsory purchase of lands under the Watford & Edgware Railway Act, 1903, an amendment of the Watford & Edgware Railway Act, 1906, and an extension of time for the completion of works, &c. A similar Bill has been deposited in the name of the Edgware & Hampstead Railway Co. The abandonment of the Southport Lytham Tramroad forms the subject of a Bill. In a general powers Bill by the Wakefield Corporation, the standby clause is included among other provisions relating to the electricity undertaking.

One of the most interesting notices is that by the Postmaster General to empower the Railway and Canal Commission to hear and determine all questions and matters of difference, which by certain indentures relating to the purchase by the Postmaster-General of the plant, property, and assets of the National Telephone Co., Ltd., are referred to arbitration.

Telegraph Traffic.—On November 19th, official notification was issued that telegrams for Honduras, Salvador, Nicaragua, and Costa Rica were subject to censorship, so that it would appear that matters were not quiet politically. An interruption occurred in the landline between Bagdad and Bassorah, and the submarine cable between Medan and Oleleh ceased working on the 21st inst. Telegrams for Kotaradja and Sabang will be sent by telephone from Pangkalanbrandan, or by post from Penang, Medan, or Pandang. The cables between Oran and Tangier and Zanzibar and Mobassa are both interrupted by reason of repairs which are being undertaken.

Improvement of the Load Factor of Central Stations.—The question of improving the load factor of central stations by utilising the energy during the hours of low load for carrying out electrochemical and electrometallurgical processes was discussed at a recent meeting of the American Electrochemical Society. The conclusion was arrived at that for many electrochemical processes, it would not pay to work intermittently or even with a reduced load for certain hours. On the other hand, intermittent working in the case of small electric furnaces, such as will probably soon be used to a large extent in steel works and foundries, would be easily possible. A case was cited of a Swiss steel plant, where energy was supplied at rates below the ordinary power rates, during certain hours, for working the electric furnaces.

Physical Society.—Among the Papers read at the meeting of the Physical Society of London on November 13th, was one by Mr. A. W. Porter, in which the author described the effect of a normal magnetic field upon the impressions made on a photographic plate placed between the terminals between which a sudden discharge is passed. The image of the spark is broadened into a band of nearly constant width, produced by the glowing gas which surrounds the spark itself. The ramifications are not modified by the magnetic field. Figures obtained when the negative terminal is on the sensitive side of the plate vary according to the surrounding gas, but when the positive terminal is on the sensitive side the figures are nearly the same for all gases. At the same meeting Mr. Porter showed an experiment illustrating the fact that when thin wires are covered with a lagging material it is not possible at once to say whether the covering will keep heat in or assist it to escape. There is a critical radius equal to the ratio of the conductivity of the material to the emissivity from its surface which the outer covering must exceed before it begins to act as a lagger. If a thin platinum wire is coated at intervals along its length with glass of about 2 mm. outer radius, and the uncoated portions raised to a temperature of 800° C., the coated portions do not even glow, but remain at about 100° C. A thickness of coating can be obtained which is such as to allow the same escape of heat as from a practically uncoated wire. To illustrate this, two narrow steam-pipes were shown—one coated with a single layer of asbestos paper, the other with a very thick coat. The two were equivalent in their power of preventing escape of heat. An intermediate thickness of coat would have made a worse-lagged pipe than either of them.

LOCAL NOTES

ACTON: *Charges against Electricity Staff.*—A long and somewhat heated discussion took place at the last meeting of the Council in connection with a number of allegations against the electric lighting staff, it being stated that in some cases men's time was charged to the Council when they were being employed upon private work for certain members of the electric lighting staff. The Electrical Engineer is to be given an opportunity of explaining the charges, and a further meeting of the Electricity Committee is to be held for this purpose.

ABERDEEN: *Tramway Undertaking.*—A concert was held last week in aid of the funds of the Aberdeen Corporation Tramways Social and Athletic Club.

BARNES: *Omnibus Co. and Street Lamps.*—A short while ago an action by the Urban District Council against the London General Omnibus Co. for damages for breaking 18 public lamps by the company's omnibuses was dismissed by the Wandsworth County Court Judge on the ground that as the omnibuses had been licensed by the police authorities the company were not liable for damaging lamp posts, unless it was shown that the drivers were negligent. On appeal Mr. Justice Bingham has reversed this decision, holding that the onus was upon the omnibus company to show that they had used reasonable care to avoid knocking down the posts In the present case, he said, it has been obviously possible to avoid knocking down the posts as it was daylight when the accidents had occurred.

BIRMINGHAM: *Tramways Undertaking.*—The Tramways Committee report that the amount expended upon street widenings to date is £238,353, whereas the amount authorised to be borrowed only amounts to £203,000. The amount spent upon the tramways undertaking including lands, buildings, rolling stock, and overhead equipment, amounts to £587,476, the authorised borrowing powers being £555,000. The Committee recommend the Local Government Board be asked to sanction the borrowing of the following sums:—Street widenings, £35,353; reconstruction of existing tramways, £32,476; and for the Coventry Road, Smallheath, and Bristol Road lines, £24,216.

BLACKPOOL: *Electric Heating.*—Mr. C. Furness, the Borough Electrical Engineer, has been carrying out some experiments upon electric heating and cooking, with the result that he hopes shortly to put a scheme before his committee for hiring out electrical stoves, &c. It is also proposed in this connection to hold an exhibition in Blackpool early next year. Mr. Furness states that a sum of £300 might be taken from the reserve fund for the purpose of providing electric heaters and cookers, which should be let out on hire at about 3s. per quarter.

BRADFORD: *Tramway Receipts.*—For the half-year to September 30th, the Corporation tramways have earned a profit of about £14,600, against £16,400 for the corresponding period of last year. The decrease is attributable to bad trade and the unemployment in the city.

BRAUNTON: *Electricity Supply.*—Messrs. Crompton & Co. are taking up the question of an electrical installation in Braunton. The scheme, if carried through, will include overhead wires. It is probable that a local company will be formed.

BRISTOL: *The Electricity Committee.*—Alderman G. Pearson has again been unanimously elected chairman of the Electricity Committee, and Mr. A. Lloyd, deputy chairman.

BURNLEY: *Tramway Brakes.*—A general meeting of the Burnley Tramwaymen's Brotherhood was held last week, when Mr. H. Mozley, the tramways manager, addressed the men on the Tramway and Light Railway Association's report on tramway brakes.

BURSLEM: *Accident at Electricity Works.*—Whilst a well sinker was being let down a well at the electricity works last week, he was overcome by an accumulation of gases and fell from the sling, a distance of about 50 ft. Owing to the state of the well it was impossible to reach him for many hours, when it was found that he was quite dead.

BURY: *The New Power Station.*—The Local Government Board have written to the Bury Corporation Electricity Committee, expressing their approval of the proposed new electricity works at Chamber Hall, which are to cost close upon £80.000, but ask for fuller details on certain points before sanctioning the borrowing of £72,000 as asked by the Corporation.

Electricity Supply.—The Electrical Engineer has reported that, for the first time in the history of the department, there has been a reduction in the output for lighting. This has been mainly due to the stoppage of works owing to the cotton trade dispute. On the other hand, applications have been received from twelve power consumers for about 222 h.p.

CAMBERLEY: *Electric Lighting Order.*—The Council has before it applications for sanction to the promotion of provisional electric lighting orders for the district by the Aldershot Gas and Water Co. and the Yorktown and Blackwater Gas Co. A committee has been appointed to consider the applications.

CAMBUSLANG: *Damages against Tramways Co.*—In connection with the death of a cabdriver through his cab coming into collision with a car belonging to the Lanarkshire Tramways Co., in December, 1907, an award of £500 damages was made by the Court of Session, Glasgow, last week.

CANADA: *Niagara Electric Power.*—A commencement has been made with the transmission lines of the Ontario Government from Niagara in connection with the new power scheme, which will supply a number of municipalities. It is not anticipated, however, that the works will be completed under two years.

CARDIFF: *Tramwaymen's Grievances.*—Mr. Arthur Ellis, the tramways manager, is still having trouble with the tramway employees in Cardiff. The present disagreement arises out of a new system of working the cars recently introduced, and the opportunity is being taken, as is usual in such cases, of comparing the general conditions upon the Cardiff tramway service to those upon other systems. The comparison, needless to say, is not favourable to Cardiff.

CARLOW: *Proposed Electric Tramway.*—The question of constructing an electric tramway or light railway from Castlecomer to Carlow *viâ* Queen's County and County Kilkenny coalfields, is under consideration. A local Committee has been formed to take the matter up.

CLEETHORPES: *Metal Filament Lamps.*—In connection with the proposed electric lighting scheme, Mr. C. S. Vesey Brown has suggested that in order to enable single metal filament lamps to be used, it would be advisable to have a small transforming station, at a cost of about £1,700, to reduce down to the necessary pressure. The committee, however, have not fallen in with the suggestion.

DEVONPORT: *Officials' Salaries.*—A scheme submitted by the Electric Supply Committee for fixing maximum and minimum limits of salaries and wages and annual increments of the employees of the electricity department has been rejected by the Council.

DEWSBURY: *Tramways Opening.*—The electric tramways between Dewsbury and Ossett were opened for traffic on Friday last week.

DUDLEY: *Tramway Matters.*—The Corporation will promote a Bill in the coming session to legalise an agreement with the British Electric Traction Co., for a lease of the tramways in Dudley.

DUBLIN: *Action against Tramway Company.*—The Dublin United Tramways Co. have been sued by a bootmaker named Martin for damages in respect of personal injuries sustained through falling off one of the company's cars. The plaintiff alleged negligence on the part of the company's servants. It appears that whilst the conductor of the car in question was on the roof collecting fares, the plaintiff left his seat in order to ring the bell from the conductor's platform for the car to stop. Whilst he was doing this, the car gave a jerk, with the result that he fell into the road and sustained the injuries complained of. The plaintiff was awarded £21 damages in the first instance, but the company appealed, and the appeal judge held that there was no negligence on the part of the company, and further stated that even assuming there had been some negligence the accident was attributable to the conduct of the plaintiff himself in going on the platform and endeavouring to manage the car himself. The decision of the first court was therefore reversed.

Fire at the City Hall.—With reference to the recent fire at the City Hall, Mr. Mark Ruddle, the City Electrical Engineer, has issued a report, in which he clearly shows that this was in no way due to the electric lighting installation. As a matter of fact, there were no electric wires anywhere near the outbreak, and the fuses in the chamber were afterwards all found to be in perfect order, and had not come into operation. Further, at the time the fire took place, the supply to the building was switched off.

GLASGOW: *Tramway Receipts.*—Since the beginning of the financial year, to June 1st, the number of passengers carried has been 102,059,107 compared with 104,483,573 in the corresponding period of last year, the receipts being £414,274, against £422,256 last year.

HANLEY: *New Plant.*—A new 500-kw. generating set was put into operation on Friday.

HERTFORD: *Electric Power Supply.*—The Surveyor in his quarterly report, states that the North Metropolitan Electric Power Distribution Co. has completed the laying of the whole of their cables, and that the cost of reinstating the roads has been repaid by them to the Council. The company has erected a refuse destructor under their agreement with the Council.

INDIA: *Power Transmission.*—It is stated that work upon a water power electric transmission scheme is about to be commenced in Simla.

JAPAN: *Electricity Supply.*—The American Vice-Consul E. G. Babbitt, of Yokohama, quotes, in a report, an article from a local newspaper on the development of the electric industry of Japan from which the following *résumé* has been made:—The authorised capital of electric undertakings in 1903, 28,500,000 yen ($14,193,000), of which 24.000.000 yen

Digitized by Google

($11,952,000) was paid up, had risen to 138,000,000 yen ($68,724,000) in 1907, of which 87,500,000 yen ($43,575,000) was paid up. The electric works undertaken chiefly represented lighting and tramways. The number of lights supplied in 1903, 365,000, had increased in 1907 to 859,143. Tokyo and Osaka require each 100,000 lights. Electric tramways show equal development. In 1903 the mileage was 38, which rose to 119 in 1907, and will be largely added to by construction during the present year. After reciting the foregoing progressive electric undertakings the newspaper article concludes as follows: "It is to be specially noted that while the works have been making steady progress not a few of the companies are in serious financial straits."

KALGOORLIE: *Electric Tramways Co.*—Owing to a number of inquiries which have been received concerning the position of the Kalgoorlie Electric Tramway Company's undertaking, and the cause of the recent fall in the prices of the company's stock, a circular has been issued by the secretary, pointing out that the company depend chiefly upon the mining population of Kalgoorlie for its revenue, and that in consequence of the reduction in the number of men employed, the net earnings for the current year at the end of September showed a decrease of about £1,000. For October, however, there was an improvement of £221. The circular also states that owing to new developments at the mines, prospects generally are brighter at Kalgoorlie than has been the case for some time past.

LAUNCESTON (TASMANIA): *Proposed Electric Tramways.* The *Australian Mining Standard* states that a plebiscite of the ratepayers is to be taken with reference to the question of issuing municipal debentures for the purpose of carrying out the proposed electric tramway system through a private company. The scheme presented by a London group of financiers has been defeated by one vote only.

LEEDS: *Guiseley Tramway.*—The work of extending the Corporation tramways from Horsforth to Guiseley has been commenced, and, with reasonably good weather, the Tramways Committee anticipate that the work will be completed by March next year. The estimated cost is about £55,000.

LIMERICK: *Action re Electric Lighting.*—An action is being taken by the Limerick Corporation against Messrs. Crompton & Co., to recover damages estimated at £1,300 for delay in the execution of a contract to deliver and erect electrical machinery in the Corporation's generating station.

LONDON: *London County Council Tramways.*—The electrification of the tramways from Brixton Police Station to Loughborough Junction, Camberwell Green, Tulse Hill, and Norwood, is now completed, and experimental runs are being made over it.

Hampstead: Supply in Hendon.—The agreement come to in 1896 between the then Hampstead Vestry and the Hendon Urban District Council, whereby the former were empowered to lay mains and supply current to premises in Hendon until the latter Council were in a position to supply electricity themselves, has been brought to an end, the Hendon Electric Supply Co. having in March last given the Hampstead Council six months' notice to terminate the agreement. The total cost of mains and services laid by the latter in Hendon was £903, and as the result of negotiations the Hendon Co. have agreed to take over for £200 certain mains which cost the Council £399. The Council are to remove their mains in Cricklewood, and it has been agreed that the cost of opening the ground and making it good, where the trench so opened can be utilised for laying the company's new mains, shall be halved.

Islington: Underground Telegraph and Telephone Wires.—Recently the Borough Council sent a circular letter to the other Metropolitan Councils, asking their support in urging the Government to lay telephone and telegraph wires underground in London. The Councils of Bermondsey, Woolwich, Stepney, Southwark, Camberwell, Finsbury and Bethnal Green have up to the present time intimated their agreement with the suggestion. The Westminster City Council, and the Borough Councils of Wandsworth and Marylebone are against the proposal. Several of the Councils are taking no action.

St. Pancras: Tramways.—The London County Council have intimated to the Council their intention to proceed at an early date with the construction of a number of important tramway routes in the district.

The attention of the Electricity Committee having been called to the fact that no charge is made to power consumers for the extra meters necessary to register the supply of current for factory lighting upon which a rebate is allowed, a minimum rate of 1s. 6d. per quarter for same is to come into operation next month.

MACCLESFIELD: *Electricity Supply.*—At a meeting of the Local Chamber of Commerce last week, the President stated that one of the greatest difficulties with regard to promoting new industries in Macclesfield is the want of electricity, which was a serious hindrance to small industries.

MONTREAL: *Street Lighting.*—In connection with negotiations which have been going on between the City Council and the Montreal Light, Heat, and Power Co., the Council has now made an offer to take a supply from the company for arc lamps at $60 per annum, but the company refuse to accept it. The present contract with the company expires on December 31st, and they suggest that the matter should go to arbitration.

PERTH: *Loss on Tramways.*—The continued loss upon the municipal tramway system is receiving some attention in local circles, it being pointed out that the total loss upon the undertaking amounts to £4,700. The question of the amount of the rate which will have to be levied to make good these losses is being regarded with some misgiving by various councillors. A proposal has been made that the undertaking should be leased to a company.

PRESTON: *Proposed Purchase of Supply Co.*—The Streets and Building Committee have appointed a sub-committee to consider the subject of acquiring the undertaking of the National Electric Supply Co.

SOUTHPORT: *Tramway to Lytham Abandoned.*—The Southport and Lytham Tramway Co., which was formed several years ago with the object of linking together Southport and Blackpool by a tram service, is about to be wound up. The company's intention was to construct a tram route from Banks, Southport, across the Ribble to Lytham and thence to Blackpool, but objections from the Port of Preston and landowners on each side of the estuary necessitated the promotion of three Acts of Parliament for time extension, which swallowed up the major portion of the authorised capital, and has resulted in the abandonment of the project.

TWICKENHAM: *Condition of Tramway Track.*—An invitation from the Town Clerk of Ealing, to send representatives to attend a further conference on the subject of the alleged noisy cars and defective tracks of the London United Tramways Co., at Ealing, on December 8th, has been accepted by the Council.

WEYMOUTH: *Proposed Tramways.*—The introduction of electric tramways is engaging the attention of the Corporation.

WREXHAM: *Electricity Undertaking.*—In criticising the details of the loan applied for in connection with the electricity undertaking, as reported in our "Tenders Invited" column, the Local Government Board Inspector said it was evident that all the previous sanctions had been pooled without any regard being paid to the expenditure under the various sections forming the total amount of the loan sanctioned for the several purposes, and remarked that it was an extraordinary coincidence that the amounts spent upon mains should be the exact amount of the over-expenditure. The Electrical Engineer (Mr. W. G. Pickvance) said that having to account for this over-expenditure, and finding no records at the Borough Accountant's offices, where all details were supposed to have been kept, the only course open to him was simply to take the cost of the latest works that had been carried out, and he had accordingly arrived at the sum by that method. The Inspector remarked that this was a very simple way of keeping accounts. In other words, the amount of £478 could not be accounted for at all, and it might easily have been spent in machinery as well as mains. There was no doubt whatever that this money had been expended on mains. The Inspector then went into the items of the loan asked for, and suggested that the loan of about £2,500 for the purpose of a new generating set, which was not immediately required, should be deferred, but pointed out that after the alterations and additions to one of the present sets had been carried out, the Board would be quite prepared to grant the extra sum when the Engineer had observed the effect of the smaller section of the extensions and the extra set was found necessary. There would be no necessity for a further inquiry. He also suggested that all meters should be bought out of revenue, but after some little discussion on the matter, the Engineer agreed to reduce his application for a loan of £300 to £100, and after this loan had been expended, meters would be purchased out of revenue. The application as eventually amended was for the sum of £4,165 in place of the £6,850 originally asked for. With reference to the Inspector's criticism of the account-keeping, with which, by the way, the Corporation officials agree, it should be pointed out that the reason for this state of affairs was that all accounts of every nature had been kept by the late Borough Accountant at offices quite away from the works, on the assumption that he, as an accountant, was better able to handle figures than the manager of the concern. Mr. Pickvance took up his post a little over twelve months ago, and one of the reforms instated is that the bulk of the accounts are to be kept by the Engineer at his own offices, and this system is entirely approved of by the new Borough Accountant.

YORK: *The Tramways Question.*—Considerable discussion took place at the last meeting of the City Council concerning the absence of information with regard to the tramways. The chairman of the Tramways Committee denied that there has been any delay in the matter, as the Light Railway Order was only sanctioned by the Light Railway Commissioners a week before the November elections, and since then the Tramways Committee had had to be reconstituted.

Manchester Local Section of the Institution of Electrical Engineers.—Owing to Mr. W. Cramp's Paper on "The Electrical Discharge and the Manufacture of Nitrogen Compound" (which was down for reading at the meeting on December 1st) having been accepted by the London Council for reading at their meeting on December 17th, it will not be read before the Manchester Local Section until December 15th.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ALGERIA.—The *Commercial Intelligence* calls attention to the fact that a municipality in Algeria, of which it has particulars, is desirous of entering into a contract for the erection of an electric lighting and tramways undertaking. The town in question is situated in the neighbourhood of important iron deposits, which are about to be exploited on an extensive scale.

BELFAST HARBOUR COMMISSIONERS.—Messrs. Preece & Cardew have prepared plans, &c., with regard to the proposed erection of a combined pumping, electric light, and power station.

BIRKENHEAD.—A Local Government Board inquiry has been held into an application by the Corporation for sanction to borrow £20,000 for the electricity undertaking.

ISLE OF THANET TRAMWAYS CO.—Additional plant at an estimated cost of £7,500 will shortly be installed in the company's power-house.

LONDON: *Hackney.*—At an estimated cost of £200, distributing mains are to be extended to the Marconi Wireless Telegraph Works, Ltd., Tyssen Street, Dalston. Mains are also to be extended to 40 Colverstone Crescent and 6 Colberg Place, at an estimated cost of £70 10s.

NEATH.—A Local Government Board inquiry has been held into an application by the Corporation for sanction to borrow £18,000 for the electricity undertaking.

RADCLIFFE.—A Local Government Board inquiry has been held into an application by the Corporation for sanction to borrow £14,350 in connection with the electricity undertaking. There was some opposition, the argument being made that it would be cheaper for the Council to take a supply in bulk from the Lancashire Electric Power Co., whose generating station is actually in Radcliffe. The inquiry was adjourned until December 2nd.

ROTHERHAM.—The Guardians have been empowered to obtain the advice of an expert in connection with the electric lighting of the workhouse.

WREXHAM.—Mr. H. Ross Hooper, of the Local Government Board, held an inquiry last week with reference to an application by the Corporation to borrow £6,850 for the extension of the electrical undertaking. Loans already sanctioned amount to £37,471, and the amount expended up to the end of March last was £57,949. The application was eventually amended for the sum of £4,165.

Miscellaneous

AUSTRALIA.—Tenders will be received at the office of the Deputy Postmaster-General, Brisbane, up till noon on January 4th, 1909, for the supply and delivery at Brisbane of cable, insulators, iron wire, covered wire, ironwork, and copper wire. Tender forms, conditions, &c., may be obtained at the Commonwealth Offices in London, 72 Victoria Street, S.W.

The Board of Trade correspondent at Melbourne (Mr. M. Hirsch) has forwarded copies of the conditions and specifications relating to the supply of telephone instruments, parts, and accessories, telegraph instruments and parts, switchboards, parts and accessories, accumulators, measuring instruments, protectors and parts, required by the Deputy Postmaster-General at Brisbane, to whom tenders should be sent by noon on January 11th, 1909. The conditions and specifications may be obtained at the Commonwealth Offices in London.

A loan of £5,000 is to be granted for extensions to the electric power station.

BRIDGEND.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £8,250. Of this amount £5,500 is for the purchase of the South Wales Electrical Power Distribution Co.'s undertaking at Bridgend, and the balance for improvements. The period of repayment is 20 years.

CROMER.—The Electric Lighting Co. are being asked to quote in connection with an extension of street electric lighting.

DOVER.—The Harbour Board invite tenders for the supply of stores during the fifteen months commencing January 1st, 1909, including electrical sundries, cables, &c. Particulars from the Registrar of Dover Harbour, and tenders by December 9th.

FELIXSTOWE.—The Council invite tenders for a Diesel oil engine and dynamo. Particulars from Mr. R. P. Wilson, Consulting Engineer, 66 Victoria Street, Westminster (fee £2 2s., returnable), and tenders by December 12th (see an advertisement this week).

HASTINGS.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £1,683 for street lighting. There was considerable opposition on the part of ratepayers, who produced a good deal of evidence that gas would be cheaper. The inquiry was closed.

LIVERPOOL.—Sanction has been received from the Board of Trade for borrowing £12,400 in connection with new tramways.

LOWESTOFT.—The Local Government Board have given their sanction to a loan of £1,000 for free wiring for twelve years.

MANCHESTER.—The Tramways Committee invite tenders for the supply and delivery of (1) steel girder tramway rails and (2) tramcar axles. Particulars from the General Manager, and tenders to the Chairman of the Tramways Committee by December 1st.

The Electricity Committee invite tenders for the supply, delivery, and erection at the Stuart Street generating station of exhaust steam, circulating water and air pump, and discharge pipes. Particulars from the Secretary, Electricity Department, and tenders by December 9th (see an advertisement this week).

NETHERLANDS.—H.M. Consul at Rotterdam announces that the Dutch Government have granted to the Flushing-Middelburg Tramways Co. powers to convert their important tramways between these two places to electric traction.

NEWCASTLE.—The Trimdon Grange Colliery Co. invite tenders for stores during the next twelve months, including electrical fittings. Tenders to the Stores Keeper, Trimdon Grange Colliery Co., Durham, by December 12th.

NEW ZEALAND.—Mr. E. E. Stark, the Dunedin City Electrical Engineer has issued a further report with regard to an installation of a further 2,000 kw. of plant in the municipal power station. His estimates are as follows:—Steam-turbine plant, £24,300; reciprocating-engine plant, £25,600; gas-driven plant, from £37,000 to £40,000.

SPAIN.—The Cia. del Tranvia Urbano de Bilbao have applied to the Direccion General de Obras Publicas of Madrid for a concession for the construction of certain electric tramway lines in the town of Bilbao. Persons desiring to compete for this concession may send in offers, on terms more advantageous to the Government, within a period of one month from November 10th.

Tenders for the installation and working of a telephone system in Ciudadela de Menorca are invited. A plan for the work, presented by Señor Conde de Torre Saure, will form the basis for tenders, and if an offer on terms more advantageous to the Government is accepted, Señor Conde de Torre Saure must be reimbursed for the value of this plan, *i.e.*, 1,000 pesetas. At equal figures the Señor will have a preference. The competition will turn on the reduction in the number of years for which the concession is desired, the maximum period being 20 years.

WARRINGTON.—Tenders are invited by the Electricity and Tramways Committee for the supply of slack coal. Particulars from the Borough Electrical Engineer, and tenders by December 10th.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

London County Council.—Tenders are invited for the installation of electric lighting, bells, and fans at the Clapham Secondary School. Particulars from the Chief Engineer to the Council, and tenders by December 1st.

E.—Memorial Hall, Stratford. Architects, G. Baines & Son, 5 and 6 Clement's Inn, W.C.

Extension of copper store, Silvertown. Builders, G. Munday & Sons, Islay Wharf, Poplar.

E.C.—Block of shops and offices, City Road, for Trustees of Sutton Estate. Architect, E. C. Monson, Grosvenor House, Acton Vale, W.

Additions, Royal London House, Finsbury Square. Architect, John Belcher, Hanover Square, W.

N.—Additions to Northern Hospital, Winchmore Hill, Highgate. D. T. Hatch, Engineer, Metropolitan Asylums Board.

Church, Finchley. Architect, Percy Lamb, 1 Clifford's Inn, W.C.

N.W.—Phthisis ward for Hendon Board of Guardians. The Clerk.

Fourteen stables, Golder's Green, Hendon. Builder, J. Gibb, jun., 191 West End Lane, West Hampstead, N.W.

Car repair shops, Edgware Road, for Metropolitan Electric Tramways, Ltd.

S.E.—Building, 188 Rye Lane, Peckham, for the Magnet Printing Press Co., Ltd.

Extension of sack building, Morden Wharf, Greenwich. A. Edmonds.

S.W.—Booking office, &c., for London & South-Western Railway Co., Battersea. Builders, Perry & Co., Tredegar Works, Bow.

Mission Hall, New Road, Battersea. Builders, Lathey Bros., New Road, Battersea.

W.—Billiard room at rear of 168 Ladbroke Grove, Notting Hill. Builders, H. Corry & Son, Pembridge Road, W.

PROVINCES.

BARKING.—Builders at Creeksmouth (in course of erection) for British Coalite Co.

Digitized by Google

BATH.—Rebuilding several blocks of shops in Avon Street, for City of Bath Charity Commissioners (£50,000). Architect, Mr. Rolfe, Belmont, Bath.

BOTHWELL (LANARKSHIRE).—Parish Council Chambers (£2,000). Architects, Beattie & Morton, 121 St. Vincent Street, Glasgow.

BRENTWOOD (ESSEX).—Central kitchen, &c., at Essex County Lunatic Asylum (£5,200). Architect, F. Whitmore, 73 Duke Street, Chelmsford.

BRISTOL.—Bank for Metropolitan Bank of England and Wales. Architects, Catley & Lawrence, 26 Orchard Street, Bristol.

BURNLEY.—Extensions to Victoria Hospital, Burnley, are to be illuminated with electricity, the whole work to cost £20,000.

CHESTER.—Freemasons' Hall, Hunter Street (£3,000). Masonic Lodges of Chester.

DARTFORD (KENT).—Church (£10,000). Architect, W. D. Caroe, 3 Little College Street, S.W.

EXETER.—New wing to West of England Eye Infirmary (£3,000). The Secretary.

FLAMBOROUGH (YORKS).—Slaughter house, stables, &c., and alterations to shop. Architect, C. F. Johnson, Westgate, Bridlington.

KILMARNOCK.—The Town Council invite tenders for the wiring of the Infectious Diseases Hospital. Particulars from the Electrical Engineer, and tenders by December 14th.

LANCASHIRE.—Female training college (£43,000), for Education Committee. H. E. Clare, clerk, County Council, Preston.

LLANDRINDOD WELLS.—Rebuilding Bridge Hotel (£9,000). Architect, A. Le Thomas, Church Street, Pontypridd.

LOWESTOFT.—Additions to hospital (£3,026) Surveyor, G. H. Hamby, Borough Council.

MAIDSTONE (KENT).—New bank for London & County Banking Co. Head Offices, 21 Lombard Street, E.C.

PLYMOUTH.—Anglican Church, Peverel Park. Architect, W. D. Caroe, 3 Little College Street, S.W.

SHEFFIELD.—Extension of Town Hall. Surveyor, C. F Wike, Town Council.

STAFFORD.—New church, Spon Lane (£4,000). Architect, E. Wood, J.P., 315 High Street, West Bromwich.

STIRLING.—Extension to Stirling Royal Infirmary (£5,000). The Secretary.

WALLSEND-ON-TYNE.—A theatre will shortly be erected here at an estimated cost of £15,000.

WARWICKSHIRE.—Secondary School (£4,405). E. Field, Clerk to County Council, Leamington.

TENDERS RECEIVED AND ACCEPTED

BRADNINCH.—The tender of Messrs. Christie Bros. & Co., for wiring the Guildhall has been accepted.

DARTFORD.—The tender of Mr. A. T. Ridley for constructing a drain for conveying water from the new condensing plant to the surface-water sewers, has been accepted at £45.

ELECTRIC TIME SERVICE.—The Synchronome Co. have installations of electric clocks in hand at the present time for the following premises :—Messrs. Selfridge & Co., Ltd., New Buildings, Oxford Street; Lloyds, Ltd., and *Daily Chronicle*, Fleet Street; Royal National Orthopædic Hospital (nurses' home and out-patients' department); St. Bartholomew's Hospital (new pathological block).

EPSOM.—The tender of Messrs. Pritchetts & Gold has been accepted for the supply and erection of a new storage battery at the electricity works, at £286.

GLASGOW.—The Tramways Committee recommend the approval of the design offered by Messrs. Somervail & Co., Dalmuir, to erect swing bridges over the Forth and Clyde Canal at Dumbarton Road and Kilbowie Road, for the purposes of carrying tramways. The plans are to be forwarded to the Caledonian Railway Co. for their approval under the terms of the Clydebank Tramway Order of 1901, and to the Board of Trade.

LEITH.—The following tenders have been accepted in connection with the Granton tramway extension :—Points and crossings, Hadfields Steel Foundry Co., £1,772; overhead equipment, Tramway Supplies (Ltd), £1,261; automatic point controllers, Tramway Supplies, £81 each; Portland cement, Johnstons, £2,040; crushed granite, James Robertson, £310; pitch and pitch oil, James Ross & Co., £1,235; tools, M. P. Galloway, £117; anchors, M. P. Galloway, £587; tie-bars, Bayliss, Jones, & Bayliss, £17; pole bases, M. P. Galloway, £50; carting, Alex. Smart, Leith, £1,108; solid drawn one-piece poles, M. P. Galloway, Leith, £1,947.

LONDON: *London County Council.*—The tender of the Anti-Attrition Metal Co. of London has been accepted for the supply of 344 pony-wheel axle bearings at 1s. 1½d. per lb.; 200 driving-wheel axle bearings at 1s. 1½d. per lb.; 100 armature bearings, 3a type, at 1s. 4d. per lb.; and 100 armature bearings, 25a type, at 1s. 5d. per lb.

The following tenders have been received in connection with the reconstruction of tramways from King's Cross to Malden Road, and the construction of new tramways in Crowndale Road. The tender contains provisions for the reconstruction of the bridge carrying Great College Street over the Regent's Canal. John Mowlem & Co. (accepted), £47,584; Mr. W. Manders, £47,642; Dick, Kerr & Co., £47,782; Mr. A. M. Coles, £53,528.

LONDON: *Thames Conservancy.*—The Engineer has reported to the Upper River Committee, that in carrying out the work at Caversham Yard, an economy of about £60 per annum would be effected if the sawmill and other machinery in the new building were driven by electricity instead of by steam, and that as the portable steam engine which now supplies the power is old, the present time is opportune for making the change. The Committee agreed to the Engineer's report, and on Monday the Board accepted the tender of Messrs. Harland, Powden & Co., Manchester, to carry out the work within six months at £220.

Metropolitan Asylums Board.—The Board has placed an order with Veritys, Ltd., at £12 12s., for electric throat lamps for the South-Western Hospital.

Holborn.—The tender of Messrs. Foote & Milne, Ltd., Victoria Street, has been accepted for the electric lighting of High Holborn Library, at £101 10s. Messrs. John Bolding & Sons, Ltd., who previously received the contract to carry out the work at £78 4s. 8d., have withdrawn on account of having made an error in their tender.

LOWESTOFT.—The following tenders have been accepted for the supply of stores for the year ending September 30th, 1909 :—White waste, 26s. per cwt., Jones, Manchester, coloured waste 20s. per cwt.; odd stores, R. Leach, Lowestoft; brass and iron screws, T. E. Thirtle, Lowestoft; wood bushes, Rudd Bros., Lowestoft; oil (crank and chamber), Vacuum Oil Co., London, 1s. 5d. and 1s. 4d. per gallon; oil (dynamo), Wakefields, 1s. 5½d. per gallon.

WEST HAM.—For some time past the Electrical Engineer has been endeavouring to dispose of demand indicators, many of which are now out of use and bad stock. The Reason Manufacturing Co. have taken 100, and the Hendon Electric Supply Co., three, and the difference on the stock price of £160 10s. and the amount realised by the sale, £22 5s., viz., £138 5s., is to be charged to net revenue account. An order has been placed with Messrs. Cory & Son for 14,000 tons of washed pea-nut coal, at 8s. 10d. per ton, delivered alongside the wharf at the electricity undertaking, for twelve months from May next.

COMPANIES' MEETINGS AND REPORTS

AMAZON TELEGRAPH CO.—The gross revenue for the year to June 30th, 1908, amounted to £84,978, and the total working expenses to £43,174. Deducting debenture interest there is a balance to the credit of the revenue account of £14,808, which reduces the debit balance to £51,070, compared with £65,878 for the previous year.

COMPAGNIE GENERALE DE TRAMWAYS DE BUENOS AYRES.—The report for the period from March 5th to June 30th, 1908, states that the company has taken up the unification of lines of a total length of 324 miles, the rolling stock consisting of 350 motor-cars and 700 trailers. The accounts for the financial year show a dividend of 4½ per cent. per annum. There is a balance of 4,235 francs to be carried forward.

DORMAN, LONG & CO.—The report for the year ended September 30th last shows a balance available for distribution of £229,383, including the balance brought forward from last accounts. The new electrically driven rolling mill (ELECTRICAL ENGINEERING, October 15th, p. 540) is ready to be started, and will be in operation in the course of a few weeks. After setting aside £20,000 towards the redemption of second debenture stock and £30,000 for depreciation, a final dividend of 4 per cent., making 6½ for the year, is recommended, carrying forward £64,710.

ELECTROMOBILE CO.—The report states that a mortgage of £20,000 has been arranged on the company's garage, and that arrangements have also been made for the issue of £40,000 6 per cent. mortgage debenture stock, the holders of which have the option of exchanging their debenture stock for ordinary shares at par, during a certain period. Re-valuation of the assets has resulted in items amounting to £15,849 being written off, and there is a deficiency shown in the accounts of £1,444. The company's capital and borrowing powers are to be further increased by the creation of 50,000 new ordinary shares of £1 each.

GENEVA TRAMWAYS CO.—The report for the year ended September 30th states that there are outstanding £5,300 4½ per

Digitized by Google

cent. debentures of the Geneva Tramways Co. (old company) to be exchanged, under a scheme of arrangement sanctioned by the Court on November 10th, 1906, for £1,590 debentures and 3,180 shares of this company. For the year covered by the accounts there was a profit of 526,818 francs, and the total balance available, after adding the balance brought forward, is 837,285 francs. After making provision for amortisation, reserve fund, and renewals fund, and a special reserve fund of 30,000 francs to meet capital expenditure, there is a balance of 372,297 francs. A dividend of 1½ per cent. is recommended, carrying forward 72,280 francs.

ISLE OF THANET ELECTRIC TRAMWAYS & LIGHTING CO.—The report for the year ended September 30th, 1908, shows a profit of £13,390. The traffic receipts, owing to the inclement weather in August and September, show a decrease of £580, but the sale of electricity shows an increase of £237 as compared with the figures of last year. The directors have pleasure in reporting that the past year was again free from any serious accident, and they have, in consequence, been able to renew the third party insurance for a year, ending in June, 1909, at a further reduction of £450. The amount of undivided revenue at the disposal of the directors is £5,516, and they propose to transfer to reserve account the sum of £2,500, bringing that account up to £5,500, and to pay a dividend of 1¼ per cent. on the preference shares, which will absorb a further £1,875, leaving £1,141 to be carried forward to the next account. It is proposed to pay the dividend on the preference shares on November 30th. The directors report that the provision of additional plant, in order to extend the lighting business of the company is urgent, and an additional installation of electric plant at an estimated cost of £7,500 is necessary to meet immediate and prospective requirements. Mr. Henry Brown and Mr. W. M. Murphy retire from the board by rotation, and, being eligible, offer themselves for re-election. The meeting is to-day.

PAIGNTON ELECTRIC LIGHT & POWER CO.—A meeting was held last week at Paignton, when the report presented showed that 6,295 shares had been allotted, the sum received being £2,448. Mr. W. J. Ham, chairman of the company, presided, and stated that although they had gone in for what some people would describe as a speculation, he believed their undertaking would turn out well both for the company and for the town itself. The directors who started the company would remain in office until 1909, and no directors' fees would be payable until the company was earning dividends. It was expected a supply would be available before Christmas. The company had entered into an agreement with the Council to erect a refuse destructor in connection with the works. It was also mentioned at the meeting that the Paignton Tramways Co. was pushing forward with its undertaking, and that in all probability a supply would be taken from the Paignton Electric Light & Power Co.

SINGAPORE ELECTRIC TRAMWAYS CO.—The report for the year to December 31st, 1907, shows a gross profit of $26,222. Debenture interest, depreciation, and royalties, however, amount to $30,775, the loss on the year's working thus being $4,552. The report states that the latter part of 1907 was marked by a heavy depression in trade amongst all classes in Singapore, and more especially so amongst the Chinese, who constitute the largest portion of the community. Consequently a very adverse effect upon the receipts was experienced, although the revenue for the year, compared with the year 1906, showed an increase of $96,262, and the passengers carried an increase of 3,271,094. The passenger receipts per car mile increased in 1907 by 11 per cent., and the working expenses showed a decrease per car mile of 3 per cent. The demand for electricity for lighting and power purposes continues to show a gratifying increase, the proportionate percentage of increase of the supply during 1907 over 1906 being 173 per cent., and for the current year to August 31st, compared with 1907, a further increase at the rate of 81 per cent.

UNITED WIRE WORKS CO.—The accounts for the year to September 30th show a profit of £6,323. Deducting the preference dividend for 1907-8, and adding £100 to the special reserve fund, there is a balance available, out of which the contractors recommend a 2 per cent. dividend on the ordinary shares, leaving £1,606 to meet the dividends accrued on the preference shares to September 30th, 1908, which absorb £1,228, leaving £377 to be carried forward.

WELDLESS STEEL TUBE CO.—The accounts for the year ended September 30th, 1908, show a gross profit of £9,673. After meeting debenture interest, preference dividend, and a dividend of 5 per cent. upon the ordinary shares, the balance of £4,301 is carried forward.

WEST INDIA & PANAMA TELEGRAPH CO.—At the half-yearly meeting last week, the report and accounts given in our last issue were adopted.

Audit of Electric Lighting Companies' Accounts.—In answer to a question in the House of Commons yesterday, Mr. Churchill stated that he had no intention of appointing any of the shareholders' auditors to act as official auditors of the accounts of the same electric lighting companies for the present year.

MISCELLANEOUS CITY NOTES

ALLIANCE ELECTRICAL CO.—Petitions for the reduction of capital from £120,000 to £60,000 will be heard before Mr. Justice Eve on December 15th

ANGLO-ARGENTINE TRAMWAYS CO.—A circular has been issued to the shareholders outlining a scheme of reorganisation which is to be submitted at an early date. It is proposed to exchange the existing £266,600 of 6 per cent. debenture stock for 4 per cent. debenture stock, ranking *pari passu* with the 4 per cent. debenture stock already issued, at the rate of £155 of 4 per cent. stock for £100 of 6 per cent. stock; to exchange the £1,300,035 of 6 per cent. cumulative first preference shares for a new issue of 4½ per cent. debenture stock, redeemable in 75 years, and ranking immediately after the 4 per cent. debenture stock, at the rate of £6 13s. 4d. of 4½ per cent. stock for each £5 first preference share, thus giving the holder the present rate of interest—namely, 6 per cent. per annum; to increase the authorised amount of the 10 per cent. non-cumulative second preference shares of £5 each by £400,000, and to convert each of the existing and new second preference shares of £5 each into two 5 per cent. cumulative first preference shares of £5 each, entitled to one vote per share. After the second preference shares have become first preference shares, to convert the existing third preference shares into second preference shares, with the same rights as at present.

BRUSH ELECTRICAL ENGINEERING CO.—Applications have been invited during the week for an issue of £100,000 prior lien 5 per cent. debenture stock, part of a total issue of £125,000. The remaining £25,000 of stock, however, will not be issued without the sanction of the holders of the £100,000 stock now offered. The stock is secured by a first mortgage in favour of the Electric & General Investments Co., as trustees, upon the freehold and leasehold land, buildings, and fixed plant of the company at Loughborough, the value of which stands in the company's books at £269,000. The stock will rank in priority, both as to principal and interest, to the other debenture stocks issued, or which may be issued by the company. The stock is further secured by a third floating charge on the whole of the remaining assets of the company. The stock may be redeemed out of the sinking fund by annual drawings at £105 per cent., or purchased in the market at a price not exceeding £105, the first redemption to take place not later than January, 1911.

COMPANIES STRUCK OFF REGISTER.—The names of the undermentioned companies have been struck off the register of joint stock companies:—Accumulator Syndicate; Californian Electric Power & Mining Development Syndicate; Dorchester & District Electric Supply Co.; Kingsbridge & South Devon Electric Lighting & Traction Co.; New Mutual Telephone Syndicate; "Vernon" Mechanical & Electrical Registers.

COMPANIES TO BE STRUCK OFF REGISTER.—The names of the following will be struck off the register unless cause is shown to the contrary within three months:—Electric Motive Power Co.; Electric Light & Power Co., of Japan; Epstein Electric Accumulator Syndicate; London Electromobile Syndicate; Nuneaton & District Light Railway Co.; Welsh Electric Traction Co.

CONSTANTINOPLE TRAMWAYS CO.—It is announced that only a portion of the new shares of this company will pass into French hands, and that only a portion of the contract for the electrification of the system will be entrusted to French firms. The greater part of the share capital is in the hands of the syndicate headed by the Continental Company of Nuremberg.

WALSALL ELECTRICAL CO.—The capital of this company has now been reduced to £20,620 from £25,000.

Students' Section, I.E.E.—The student-members of the Institution who attended the first annual smoking concert, held on Tuesday evening at Stone's Restaurant, The Broadway, Ludgate Hill, with the idea of spending an enjoyable evening, were not disappointed. There was a good attendance, and an excellent and varied programme of entertainments had been arranged. Songs were given by Mr. C. B. Nadaud (chairman), and Messrs. Allisstone, Dolleymore, Driver, Ellis, and Sack; the humorous songs of Mr. Selwyn Driver were particularly appreciated. Mr. G H. Stevens (hon. secretary) contributed some piano selections, and Messrs. Engelbach, Knight, and H. Nadaud also assisted.

The Johannesburg Gas Plant.—The Johannesburg Municipal Council is taking action against Messrs. D. Stewart & Co. (1092), Ltd., of Glasgow, and Messrs. Beardmore & Co., of Glasgow, claiming £400,000 in respect of the Johannesburg gas-driven generating plant. The defendants pleaded that the matter should be dealt with by arbitration, and further deny breach of contract, claiming that the installation was in full accordance with the specification of the plaintiffs. It is further claimed that any failure of the plant to reach the prescribed tests was due to the unsuitability of the coal used by the plaintiffs. The Glasgow Court has decided that the action shall proceed.

Digitized by Google

APPOINTMENTS AND PERSONAL NOTES

The Swansea Harbour Trustees will shortly be advertising for a manager of the harbour electric power station, at a salary of £250 per annum.

Applications are being invited for "A" and "B" class station supervisors at the Hong Kong Dockyard. (See an advertisement this week.)

On Friday last the members of the staff of the Loughborough Corporation Electricity Department presented Mr. W. Allcrott, who has completed his pupilship, and is leaving to take up an appointment with the Valvoline Oil Co., Ltd., at their Birmingham branch, with a combined letter wallet and pocket book, fountain pen, and pocket steel tape.

The salary of Mr. R. Jones, station engineer at the Dartford electricity works, has been increased from £130 to £140 per annum as from January 1st next, with a further increase of £10 on January 1st, 1910.

For the position of junior assistant engineer at the Leek electricity works, Mr. F. H. Minchin has been appointed at a salary of 25s. per week.

Mr. George Verity, chairman of Veritys, Limited, left England on the 19th for India, Singapore, &c., on a combined business and holiday trip. He is due to return early in March, when he takes up his duties as High Sheriff for the County of London, an office which was held on a former occasion by his brother, the late Mr. John B. Verity.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, quoted on Tuesday night, net c.i.f. port of arrival, was £65 10s. to £66 per ton (last week, £66 10s. to £67 per ton).

"AUTOMAT" LAMPHOLDERS.—Owing to the large demand for "Automat" lampholders since their introduction some few months ago, the Metallic Seamless Tube Co., of Birmingham, have been compelled to increase very considerably their works' capacity for dealing with same. Stocks have also been considerably increased in order to be able to meet the large demand promptly.

BRITISH ELECTRICAL FEDERATION.—The offices of the British Electrical Federation have been removed to Electrical Federation Offices, Kingsway, London.

CRYPTO ELECTRICAL CO.—Owing to the difficulty which has been experienced in getting through on the telephone, and to the increase in their business, the Crypto Electrical Co. have found it necessary to instal a second telephone, the number of which is 12831 Central.

MARRYATT & PLACE.—This firm, of 28 Hatton Garden, London, will in future be carried on under the style of Marryatt & McNaught, Ltd., so far as the manufacturing business at the Askew Works, Shepherd's Bush, London, is concerned. The other portions of the firm's business are unaffected by the new arrangement.

WORKS FOR SALE.—An extensive factory recently erected on the Osmaston estate, Derby, is for sale. (See advertisement this week.)

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A meeting of the Llandudno & Colwyn Bay Electric Traction Co. will be held at the offices of Messrs. Josolyne, Miles & Blow, 21 Spring Gardens, Manchester, to receive the liquidator's account of the winding up.

NEW PUBLICATIONS

"Elementary Manual on Steam and the Steam Engine." By Andrew Jamieson. Twelfth edition. (London: Charles Griffin & Co.) Price 3s. 6d.

"Elementary Dynamo Design." By W. B. Hird. (London: Cassell & Co., Ltd.) Price 7s. 6d.

"Essays Biographical and Chemical." By Sir William Ramsay. (London: Archibald Constable & Co., Ltd.) Price 7s. 6d.

The Census of Production and the Electrical Trades.—Some few months ago the form, which is to be sent out to manufacturers and engineers in the electrical industry for the purpose of obtaining statistical information in accordance with the Census of Production Act of 1906, was published, and we gave its main features on page 41 of our issue of July 2nd. A special form intended for the general and electrical engineering trades has now been published. This contains only a few of the questions which were included in the previously issued form, and is divided, as before, into two parts—namely, compulsory and voluntary information. Questions relating to capacity of power plant, consumption of copper, constructional work on own buildings, and similar questions which concern only the manufacturer, are omitted.

NEW COMPANIES

J. V. COONAN.—This company was registered on November 10th, with a capital of £1,000 in £1 shares, to take over the business carried on at Church Row, Cleveland Street, Hull, as "J. V. Coonan," and to carry on the business of mechanical engineers, manufacturers of and dealers in all or any apparatus and things capable of being used in connection with the use of steam, electrical, or motive power or otherwise. Private company. The number of directors is not to be more than five; J. V. Coonan is the first. Qualification 50 shares. Registered by C. Doubble, 14 Serjeants' Inn, E.C.

C. GAINER.—This company was registered on November 18th, with a capital of £1,000 in £1 shares, to carry on the business of horticultural, constructional, electrical, mechanical and general engineers, manufacturers of rolling stock, metal and wood workers, &c. Private company. Table "A" mainly applies. Registered office, Western Works, Railway Place, Bath.

GILLINGHAM ELECTRIC & STEAM LAUNDRY CO.—This company was registered on November 9th, with a capital of £2,500 in £1 shares, with objects as indicated by the title. Private company. Table "A" mainly applies. Registered by C. Doubble, 14 Serjeants' Inn, E.C.

LIGHT RAILWAY & GENERAL CONSTRUCTION CO.—This company was registered on November 20th, with a capital of £1,000 in £1 shares, to construct or acquire and turn to account light railways and tramways in the United Kingdom and abroad, &c. Private company. The number of directors is not to be more than four; the subscribers are to appoint the first. No qualification required. Registered by Paines & Co., 14 St. Helen's Place, E.C.

MIDGLEY & SIMPSON.—This company was registered on November 19th, with a capital of £1,000 in £1 shares (996 preference), to acquire the business of electrical, mechanical, and consulting engineers carried on by C. A. Midgley and D. H. Simpson, as "Midgley & Simpson," at Leeds. Private company. The number of directors is not to be less than two nor more than five; the first are C. A. Midgley, D. H. Simpson, and two others to be appointed by the subscribers. Qualification, £250. Remuneration as fixed by the company. Registered office, Aire & Calder Navigation Collieries, Bridge End, Leeds.

MUNSTER ELECTRIC LIGHTING CO.—This company was registered on November 14th, with a capital of £2,000 in £1 shares, to acquire the business of general electricians and contractors, electric light contractors, &c., carried on by J. Hunter, C. H. Wright, J. O'Keeffe, E. Griffiths, and R. H. Bindloss, as the "Munster Electric Co.," at Fethard, Tipperary. Private company. The number of directors is not to be less than two nor more than seven. Qualification left blank in articles. Remuneration as fixed by the company. Registered by Kerr & Lanham, 16 Furnival Street, E.C.

PEMSEL & WILSON.—This company was registered on November 18th, with a capital of £1,000 in £1 shares, to adopt an agreement with A. F. Pemsel, W. L. Wilson, and H. J. Pemsel for the acquirement of the business of motor, electrical, and general engineers and constructors carried on by them, and to carry on the said business and that of electricians, manufacturers of and dealers in motors, motor cars, cabs, cycles, &c. The subscribers are A. F. Pemsel, Hemel Hempsted, Herts, engineer, and W. L. Wilson, A.M.I.M.E., Hemel Hempsted, Herts. Private company. The number of directors is not to be less than two nor more than five; the first are A. F. Pemsel and W. L. Wilson. Qualification, £25. Remuneration as fixed by the company. Registered office, London Road, Apsley End, Hemel Hempsted, Herts.

REGENT ELECTRIC CO.—This company was registered on November 7th, with a capital of £100 in £1 shares, to carry on the business of manufacturers of and dealers in "Holmquist" and other electric light baths, mercury-vapour lamps, and their appliances, electrical engineers, &c. The subscribers are C. M. Holmquist, 52 Regent Street, W., electrical engineer; H. Curry, 9 Priory Grove, South Kensington, S.W., electrician. Private company. Table "A" mainly applies. Registered office, 46 Irongate Wharf Road, Paddington, W.

ROBINSON & HANDS ELECTRICAL CO.—This company was registered on November 20th, with a capital of £1,000 in £1 shares, to carry on the business of manufacturers of and dealers in electrical and gas fittings and accessories, &c. The subscribers are A. C. Robinson and W. C. Hands, 54 Barwick Street, Birmingham, electrical engineers. Private company. The number of directors is not to be less than two nor more than five; the first are A. C. Robinson and W. C. Hands. Qualification, 10 shares. Registered office, 54 Barwick Street, Birmingham.

WEST KENT ELECTRIC CO.—This company was registered on November 11th, with a capital of £100 in £1 shares, to carry on the business of electricians, electrical, mechanical, metallurgical, and chemical engineers, &c. Minimum cash subscription, £20. The number of directors is not to be less than two nor more than seven; the first are P. H. Martin and G. E. Bird. Qualification £10. Remuneration as fixed by the company. Registered by Minet, Pering, Smith & Co., 7 St. Helen's Place, E.C.

Digitized by Google

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Nov. 19th, 1908

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

1907 Patents

26,940, **Resistance Wire Alloy.** British Thomson-Houston Co. (*General Electric Co., U.S.A.*). An alloy which does not easily oxidise at even a red heat, and which resists the action of moisture and acids, is described in this specification. It consists of 62 parts by weight of nickel, 20 parts iron, 12 5 parts chromium, 5 parts manganese, and traces of silicon, carbon, and phosphorus. It can be rolled and drawn, and has a specific resistance 70 times that of copper. In the preparation of the alloy, hematite is first introduced into the crucible to decarbonise the nickel, and then the iron and other ingredients are added in succession. Clay-lined crucibles must be used. Four claims.

28,619, **Active Material for Accumulator Plates.** E. C. Ekstromer and M. Ekstromer. The usual active material, which consists of a metallic oxide formed into a paste, is not sufficiently porous to allow the evolved gases to be readily passed off, and for this reason the plates have a tendency to buckle. This invention relates to a new substance, which consists of an albumenoid, such as gelatine, that has been treated so as to be rendered porous and elastic. When this substance is mixed with the active material, the tendency to buckling is said to be overcome, sulphating diminished, and the life of the battery prolonged. Three claims.

1908 Patents

72, **Production of Undamped Electrical Oscillations.** S. Eisenstein. According to this invention it is proposed to use a Wehnelt cathode-ray tube, the cathode of which consists of a platinum plate coated with an alkali oxide, as the oscillator in an oscillating circuit connected on Duddell's system. It is stated that this gives better effects than when a mercury vapour lamp is employed, as regards the production of undamped oscillations. One claim, one figure.

661, **Armature Winding.** E. F. W. Alexanderson. If, in armature windings, only two coils per slot are employed, the leakage reactance between adjacent coils is equally distributed, but if more than two coils per slot are used, this is not so. According to this invention, the leads from the armature coils to the commutator segments are carried once across the armature at the bottom of the slots, and by suitably disposing these in the slots, the inequality in the reactances can be compensated for if four coils per slot are used. By carrying the leads twice across the armature, six coils per slot can be used. Three claims, five figures.

8,416, **Compound Metal Filaments.** Wolfram-Lampen Aktien Gesellschaft. This specification relates to metal filaments for incandescent lamps, consisting of an inner core of sintered niobium, osmium, vanadium, thorium, titanium, or zirconium, or alloys of these metals, with a coating of tungsten. Such filaments can be sintered to a higher degree than a pure tungsten filament, and are therefore stronger; they have also a high specific resistance, and, according to the specification, can be run at 0·5 watt per candle without a blackening of the bulb. The process of manufacture is to coat a filament of carbon and one or more of the above highly refractory metals, with a tungsten paste. The whole is then sintered together and the carbon expelled in the usual manner. The porous internal structure obtained causes the filament to have a very high specific resistance. Three claims.

14,763, **Construction of Commutators.** Akt. Ges. Brown, Boveri & Cie. The special mode of construction described in this specification consists in the use of discs, which are axially elastic, and are mounted on the shaft for supporting shrinking rings shrunk on the ends of the commutator. By the use of such elastic discs, the relative expansion between the shaft and the commutator segments is allowed to take place without friction. Apertures may be made in the walls of the discs to assist the cooling of the commutator. Two claims, two figures.

16,986, **Flywheel Motor Set for Intermittent Loads.** Société Anonyme Westinghouse and R. Brun. This flywheel set consists of a main continuous-current compound-wound motor, to which is coupled a flywheel and an auxiliary generating machine. The armature of the auxiliary machine is put in series with the series winding of the main motor and connected across a resistance which is in series with the main motor. The field winding of the auxiliary machine is connected across a portion of this resistance, and the shunt winding of the main motor is connected across the supply mains. When the motor is running light, the E.M.F. generated by the auxiliary machine exactly opposes the E.M.F. across the resistance, but when the motor is loaded, the latter E.M.F. predominates, with the result that a current flows through the motor series winding, reducing the speed of the set, so that energy is taken from the flywheel. Not only does the E.M.F. across the resistance increase, but the iron of the auxiliary machine becomes saturated; this, together with the drop in speed, augments the effect. In a modification of the above system, the auxiliary machine has two opposing field systems, one of which becomes saturated before the other, and produces a resultant E.M.F. in the motor series winding circuit, when the load comes on. Four claims, three figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

1907 Patents

17,635, Milton. Inductor generators.
17,743, Marino. Metallisation of vitreous surfaces so that metal may be electrolytically deposited on them.
23,916, Latour. Single-phase machines.
23,977, Brown & Dearlove. Telegraph apparatus.
23,988, Harrison & Dorman. Process for producing tungsten metal combinations.
24,006, British Thomson-Houston Co. (*General Electric Co., U.S.A.*). Electromagnetic relays.
24,234, Reid. Magneto generators.
24,283, Schoop. Welding aluminium.
24,343, Cox, & Edison & Swan United Electric Light Co. Signal lamps.
24,404, Sunderland Forge & Engineering Co., & Blair. Hauling and winding apparatus.
24,550, Fennell & Perry. Electric radiators.
24,933, Gese. Devices for indicating the extent of the charge or discharge of an accumulator.
25,842, Irwin, Robson, & Cook. Distribution of power by transformers.
25,923, Maley. Track brakes for rail- or tram-cars.
27,958, Thomson. Brakes for railway- and tram-cars.

1908 Patents

218, Douse. Steam turbines.
425, Hytten. Telegraphone apparatus.
980, Ransford (*Manson*). Apparatus for straining telegraph and telephone wires.
2,294, Tunbridge. Nut for the terminals of accumulators.
2,492, Wengelin. Means for controlling lamps from a distance.
3,049, How & Partington. Electric connections.
3,391, Leitner. Variable-speed dynamos.
3,602, Jamieson. Steam turbines.
3,662, Kilroy, Needham, & Evershed & Vignoles, Ltd. Apparatus for the production of sound in air or water.
4,371, American Electrical Novelty & Manufacturing Co. Speed indicators.
6,605, Morrison. Lamp globe gallery.
6,939, Royer. Ignition apparatus for explosion engines.
9,620, Bonn & Jones. Hand-fed arc lamps.
9,682, Turner. Fluid pressure brakes.
10,098, Ward & Stevens. Filament for glow lamps.
11,175, Kohler & Kohler. Electrical operation of tramway points from the vehicles.
11,945, Mitchell. Surface contact traction systems.
12,580, British Thomson-Houston Co. (*General Electric Co., U.S.A.*). Alternating-current commutator motors.
13,397, Hill & Read. Lock with automatic bell alarm.
13,852, Delage & Woog. Incandescent gas lamps with electric ignition.
15,746, Lafitte. Long distance lighting.
15,875, Moonen. Sparking-plugs for explosion motors.
20,601, Siemens Bros. & Co., & Ferreira. Electrically-controlled railway signals.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

1908 Patents

5,089, Savart & Graindorge. Electric tremblers.
18,523, Schmelzer. Metallurgical furnaces.
20,005, Fessenden. Electric signalling.
21,263, Fessenden. Electric transmission of energy.
21,385, Siemens & Halske Akt.-Ges. Metal filament lamps.
22,236, Basset. Electric batteries.
22,562, Voigt & Haeffner Akt.-Ges. Distributing stations.
22,824, Soc. d'Electro-Chimie. Electrolytic production of sodium.
22,951, Schollenberger. Combined trolley wheel and sleet cutter.
23,489, Snook. High potential rectifying switch.

Registered as a Newspaper.

NO. 101 [VOL. IV., NO. 23] THURSDAY, DECEMBER 3, 1908. [PRICE ONE PENNY.

ELECTRICAL ENGINEERING.

The Engineering Journal of the Electrical Industry

PUBLISHED EVERY THURSDAY. Price **1d.**

SUBSCRIPTION RATES.

United Kingdom. 6s. 6d. per Annum.

Canada. 8s. 8d. per Annum.

Other Colonies and Abroad. 13s. per Annum.

Small prepaid Advertisements for SITUATIONS VACANT AND WANTED, ARTICLES FOR SALE AND WANTED, &c., are inserted at the rate of One Penny per word, minimum One Shilling, three insertions for the price of two.

OFFICIAL NOTICES and TECHNICAL COLLEGE ANNOUNCEMENTS are inserted at the rate of Ninepence per line (column width).

Other Advertisement Rates on Application

Latest Time for Receiving

Letters for Insertion, *Tuesday first post.*

Small Advertisements and Official Announcements *Wednesday first post.*

Displayed Advertisements, *Tuesday first post.*

Corrections in Standing Advertisements, *Monday first post.*

All letters to be addressed to "Electrical Engineering," at the EDITORIAL AND PUBLISHING OFFICES: 203-206, TEMPLE CHAMBERS, LONDON, E.C.

Telegrams: "Circling, London." Telephone No.: 5509 Holborn.

Cheques to be made payable to THE KILOWATT PUBLISHING CO., LTD., and to be crossed LONDON AND WESTMINSTER BANK (Temple Bar Branch).

Binding Cases for Vol. III. may be obtained, price 2s. each, post free 2s. 4d. Readers can have their volumes bound by their own bookseller; or they may send their numbers to us, carriage paid (with the reader's name and address), and a remittance of 4s 6d. under separate cover. The volumes will then be bound and returned carriage paid to any address in the United Kingdom, or carriage forward to the Colonies or abroad.

"Electrical Engineering," although the Cheapest Electrical Paper (Price 1d. weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

A NEW telephone exchange is approaching completion in Cardiff, where hitherto the Post Office and National Telephone Co. have been in competition. The new exchange has been built by the Post Office, and is to be rented to the National Telephone Co. (whose existing exchange is full) until the expiry of the company's license in 1911. A feature is a new subscribers' operator's cord circuit, in which the repeating coil is not employed. (Page 721.)

AT this evening's meeting of the Borough Council of St. Marylebone, the proposal to adopt electric lighting in all the streets in the borough in which mains are laid will be discussed. It is proposed to use the old gas lamp-posts, merely substituting two metal-filament lamps for the present incandescent gas fitting in each lamp, and to connect each lamp-post separately to the ordinary service mains. The Lighting Committee would pay an annual sum to the Electricity Department which would bear all capital charges connected with the change over. (Page 724.)

MR. W. R. Cooper, in his Paper read last Thursday before the Institution of Electrical Engineers, considered the various methods of charging which had been proposed from time to time in relation to a supply both for lighting and domestic heating and cooking. He condemned all existing systems, especially the maximum demand system, and proposed one involving the payment of a fixed sum per annum, based on the total wattage of the lamps installed, plus $\frac{3}{4}$d. per unit used. The latter portion dealt with electric cooking and domestic heating in a somewhat superficial manner. The discussion turned principally on the first part of the Paper, but no satisfactory agreement was arrived at as to a suitable tariff. The general opinion expressed, however, was that the progress of electric heating and cooking was not so much a question of tariff as of the cost and design of the apparatus. A long communication was received from Mr. F. A. Wilkinson (Electrical Engineer and Manager, Marylebone), which gave the results of practical experience in electric heating and cooking, and definite figures of current consumption. (Page 725.)

Digitized by Google

MR. G. C. Lloyd, who has been secretary of the Institution of Electrical Engineers since 1904, has been appointed secretary of the Iron and Steel Institute, in succession to the late Mr. Bennett H. Brough. (Page 729.)

THE proposal of the German Government to impose a tax on electricity, gas, and illuminating apparatus is meeting with considerable opposition. A committee of representatives of the various branches of the electrical and gas industries has been formed for the purpose of collecting information and of organising opposition to the Bill. In an article in a German contemporary, Dr. Fasolt criticises the statements made in the explanatory memorandum published with the Bill, and points out that the tax will affect the working classes quite as much as the upper classes, and is therefore not a tax on a "luxury." We give some figures, showing the probable influence of the tax on the cost of coal mined in the Ruhr district. (Page 730.)

LETTERS appear in our correspondence columns replying to an inquiry for small remote control switches, and relating to the losses in small 25-volt transformers. A correspondent also describes an interesting method of obtaining unusual frequencies for testing purposes. (Page 730.)

IN a Paper on the application of storage batteries to alternating-current systems, read before the American Institute of Electrical Engineers by Mr. L. Woodbridge, the author discusses the most suitable methods of regulation for various different conditions of load. Preference is given in a number of instances to the "split-pole" converter, and a special type of exciter is also described for controlling the field of a booster or split-pole converter, in response to variations of load on an alternating-current system. (Page 731.)

THE reading of Mr. W. N. Y. King's Paper on natural and induced draught was followed by a discussion, in which a number of well-known engineers took part. The basis on which a comparison of cost should be made was discussed, and several speakers emphasised the desirability for entirely re-designing a natural draught system, if it is to be converted to induced draught. Several combined systems were mentioned. (Page 734.)

THE Fire Brigade Committee of the London County Council have presented a report dealing with fires upon tube railways, in which certain recommendations are made with regard to inspections of the fire appliances, automatic indicators showing when the current is on or off, &c. (Page 734.)

IN a Paper read recently before the Rugby Engineering Society, Mr. J. Findlay dealt with the subject of carbon and tungsten filament incandescent lamps, and urged the view that it was uneconomical to run tungsten lamps at an efficiency higher than 1·25 watts per c.p. (Page 735.)

A SHORT article describes an improved form of alternating-continuous converter for charging accumulators and similar purposes. (Page 735.)

UNDER "Electrometallurgy and Electrochemistry" a new and partly electrolytic method of winning copper is described, and a note is given on a German patent connected with the preparation of electrolytic zinc. (Page 736.)

WE give particulars of some further Bills which will be promoted in the next session of Parliament. (Page 736.)

A DEPUTATION of the London County Council waited upon the Prime Minister on Thursday, urging the creation of a Traffic Board for dealing with locomotion questions in London, as recommended by the Royal Commission in 1905. The Prime Minister replied that his own opinions were rather that London suffered from a superfluity of authorities in this connection, but promised that the proposal should have consideration. (Page 736.)

BOTH the London Electric Supply and the London (Westminster and Kensington) Electric Supply Bills have been passed by Sir Luke White's Committee of the House of Commons, and reported for third reading. The former Bill contains provisions constituting the London County Council the purchasing authority of eight of the London companies in 1931, the Council being compelled to give three years' notice of their intention to purchase, and to furnish the companies with the necessary capital for developing their undertakings during the period of notice. Should the Council not purchase in 1931, it may purchase at subsequent periods of ten years. The County Council has not been constituted the purchasing authority of the companies named in the second Bill, but should legislation be promoted in the future to this effect, the companies have pledged themselves not to oppose. A report has been issued by the Parliamentary Committee of the London County Council, in which strong exception is taken to the provisions in the London Electric Supply Bill, in so far as these concern the Council, and a recommendation that the Bill should be opposed, unless drastic alterations are made, was carried at Tuesday's meeting. Notice to reject the Bill on third reading has been given by five members of the House of Commons, four of whom are members of the London County Council. A deputation representing 15 metropolitan borough councils and 13 local authorities owning electricity works outside the County of London waited upon the President of the Board of Trade on Thursday to ask the Board of Trade to assist in the passing of the later subjects in the Electric Supply Bill, and also to re-introduce the Electric Supply Bill which was introduced several sessions in succession by the Board of Trade, one of the main provisions of which was to enable electrical undertakings to give and take supplies of electricity in bulk. Mr. Winston Churchill replied that as the Bill just passed by Sir Luke White's Committee only dealt with the County of London, it would be necessary for the Board of Trade to re-introduce the other Bill, which would allow authorities outside the metropolitan area to link up in a similar manner. (Page 741.)

AMONG the specifications published by the Patent Office on Thursday last is one by Q. Marino, in which a process for preparing vitreous surfaces for electrolytic deposition is described. A specification by F. Harrison and C. H. Dorman relates to the manufacture of an organic compound of tungsten, which is a conductor of electricity, and an improved flux for use in the welding of aluminium is covered by a patent granted to M. U. Schoop. In a specification by C. W. Cox and The Edison & Swan United Electric Light Co., Ltd., a high-tension vacuum tube lamp for flash signalling purposes is described. An electromagnetic coupling for electric cranes, hoists, and winding-gear is the subject of a specification by The Sunderland Forge & Engineering Co., Ltd., and W. Blair, and another by J. T. Irwin, W. E. Robson, and J. L. Cook relates to automatic switches for auto-transformers. A split-tube cable-connector has been patented by H. D. How and W. W. Partington, and a patent for an improved lamp-globe gallery has been granted to A. Morrison. A patent by G. J. Schoeffel for an electrically controlled steam whistle expires during the current week. Abstracts of all of the above specifications are given in our Patent Record. (Page 740.)

A FURTHER offer has been made to the Acton Urban District Council by the Metropolitan Electric Supply Co. for a supply in bulk. The rate now quoted is £5 per kilowatt per annum of maximum demand, plus 0·33d. per unit; but the Council have instructed the

Digitized by Google

Town Clerk to negotiate with the company for the complete working of the Council's undertaking.—The Bridgend Council has formally taken over the local power station of the South Wales Power Co.—An offer by the Reason Manufacturing Co. to provide electric radiators at a quarterly rental in Brighton, the Corporation merely to collect the accounts, has been accepted.—An agreement has been entered into with the Poplar Borough Council by the L.C.C. for the lighting of Blackwall tunnel.—The Stepney Borough Council has before it a report by its Works Committee, protesting against the suggestion in the report of the Board of Trade Traffic Department that it is impossible to use the conduit system in the Mile End Road.—Damages to the extent of £200 have been awarded to a passenger who was injured on the Manchester Corporation Tramway system.—An offer has been made by a British syndicate to purchase the St. Petersburg Municipal tramway system.—The Weymouth Corporation is considering the trackless trolley system. (Pages 741-742.)

A 2,500 kw. turbo-alternator is required by the Cardiff Corporation; motors of various sizes are required by the Birmingham Corporation; and electrical stores by the Edinburgh and District Tramways Co. and the Powell Duffryn Steam Coal Co. New plant to the extent of £7,000 is to be installed by the Sheffield Corporation; a loan of £9,000 is to be taken up by the Hammersmith Borough Council; 33,000 incandescent electric lamps are required by the Melbourne City Council, and an expenditure of £250,000 is contemplated upon the telephone service in Austria. The Salford Corporation have accepted the tender of Messrs. Balcke & Co. for water-cooling plant at £12,344, and the tender of the British Thomson-Houston Co. for a turbo-alternator at £2,400 has been accepted by the Watford Council. (Pages 742-744.)

The scheme of arrangement in connection with the reconstruction of Messrs. Bruce, Peebles & Co. has now been sanctioned by the Courts, and the first directors of the new company have been appointed. It is stated that the accounts of the South Wales Electrical Power Distribution Co., when made up at the end of the year, will show that the reconstruction has been successful. (Page 745.)

The rejection of the London and District Electricity Supply Bill would seem, if anything, to have accentuated the difficulties surrounding the unification of the existing supply undertakings in the metropolis. The net result of the prolonged Parliamentary proceedings this session is that the London County Council, through the medium of some of its members, who also sit in the House of Commons, has taken upon itself —in the absence of certain proposed amendments—the responsibility of blocking both the Bills dealing with the purchase of the companies' undertakings, which were passed by Sir Luke White's Committee last week. The present position, it is to be feared, is largely due to a want of clearness on the part of the Government in their pronouncements upon the subject, which has been reflected in a marked degree in the various decisions of the House of Commons Committee to which the interpretation of the Government instructions was subsequently entrusted. Thus, although in respect of eight companies, the London County Council is constituted the purchasing authority in 1931, yet the question of who shall purchase the West End companies is left over for future legislation, which may or may not be successfully resisted. But the real point upon which the County Council has determined to take drastic action concerns the terms of purchase. The instruction to the Committee stated that the County Council shall purchase "upon equitable terms," and it appears as if the companies, as the result of a conference with the Board of Trade, have been led to believe that this signified, as the Committee have construed it, something over and above the ordinary terms of the Electric Lighting Acts, in consequence of the increased value of the undertakings, due to the linking up. To this the strongest possible objection was taken before the Committee by the London County Council, but without avail. To add to the confusion of ideas on the subject, Mr. Winston Churchill's remarks to a deputation on Thursday amount to the statement that whilst the Department were prepared to facilitate linking up between the undertakings inside the county with those outside, every effort must be made to prevent the companies getting terms any more advantageous than those set forth in the Electric Lighting Act of 1888. Thus the views of the companies as to what they had been promised, the views of the Committee regarding the announcements of the Board of Trade, and the intentions of the Board of Trade itself would seem to be all at variance, and we are afforded the spectacle of both parties at Spring Gardens united to prevent the companies securing advantages, under their Bill, which would not have come to them had the original position remained unchanged. This aspect of the question, of course, leaves out the great advantage to the County Council of having a more or less complete undertaking handed over to it in 1931, instead of a number of isolated undertakings, upon which large sums of money would have to be spent for the purposes of consolidation. But however all this may be, there seems little desire on the part of the authorities to deal with the problem in a statesmanlike manner, although no clear reason exists why this should be so.

Mr. W. R. Cooper's Paper at last Thursday's meeting of the Institution of Electrical Engineers dealt with a subject about which comparatively little is known, and neither the Paper nor the discussion can be said to have added much to this small sum total of knowledge. The points which appear to have been most clearly brought out were the unsuitability of every existing tariff system for a mixed lighting and heating load, and the hesitation that is being shown in adopting such heating and cooking apparatus as is already obtainable, partly from ignorance, partly on the score of high first cost, and partly from the idea that the running costs of electric heating and cooking are prohibitive. The tariff question is not one that will be solved until more is known about the proportions and nature of the load that will arise when electric heating and cooking have come to stay, when possibly Mr. Mordey's dream of a universal flat rate will be realised. In the meantime, as additional wiring is practically always necessary on account of the heavier current, the separate-circuit system, with all its disadvantages, will probably continue to be used, except in cases of a few small radiators, where plug meters can be employed. Apart from cooking, domestic electric heating seems to be already finding its own place, and this is strikingly shown in the figures relating to the growth of the heating load at Marylebone on page 729. For large rooms, general house-heating and long-

Digitized by Google

hour purposes, electric heating at present supply prices is practically out of the question, but for bedrooms, small sitting-rooms, and the like, its comfort, cleanliness and economy are rapidly receiving their due appreciation. It may also be said that the convenience of such appliances as electric flat-irons, and other small domestic utensils, only requires to be known to lead to their very general adoption, although the amount of current they take is too small to materially affect the question. The subject of electric cooking is somewhat different. Very little is known either of actual running costs or the behaviour of the apparatus now obtainable in the hands of the English cook, and even the author of the Paper had to admit that he did not speak from experience. Such experiments as have been carried out—and as to these Mr. Wilkinson's communication is of value—appear to indicate that with a reasonably low cost of energy, the working cost does not compare unfavourably with that for gas, while its greater cleanliness makes it far preferable. The expense of maintenance, like that of first cost, will not reach a steady state for some time to come, as it is only extended experience which can lead to improvements in construction, which will minimise the wearing parts, and ensure their easy and cheap replacement. A great deal has been done already in this direction, and it is only increased activity on the part of both supply authorities and manufacturers which can lead to that appreciation of the facilities already available which will give the impetus necessary for further progress.

THE arguments placed before the Prime Minister last week by the deputation of the London County Council, which urged the creation of a Traffic Board for London, did not exactly put into effect the recommendations under this head of the Royal Commission on London Traffic in 1905. All that the County Council seem to require carried out would seem to be quite capably done at the present time by the Special Traffic Branch of the Board of Trade; we might almost say more capably done than would be the case with an elected body. The Royal Commission on London Traffic obviously intended that its proposed Traffic Board should exist in a much more tangible form than a mere adviser, whose opinions might or might not be acted upon. Reading between the lines, it was evidently intended that all schemes affecting locomotion and transit in the whole of Greater London should be examined, in co-operation with the parties promoting them, and a report presented to the Parliamentary Committee considering them, and that this report should be treated as an official communication, upon which the Committee would be bound to act, much in the same way that reports from the Local Government Board and the Board of Trade are regarded at the present time. Such a Traffic Board must be endowed with official powers far in advance of those of an advisory body pure and simple, otherwise the whole object of its existence would be rendered nugatory. That this was the feeling which prompted the wording of the report of the Royal Commission is evident from the expression of opinion that, after scrutiny by the Traffic Board, there would be no necessity for Bills to go before two Parliamentary Committees, as is at present the case, but that having been previously investigated by the Traffic Board, schemes would need only to be considered by one Committee or a Joint Committee of both Houses. Unless this attitude were taken up in relation to the constitution of such a Board, there would be little justification for its existence, for, as pointed out by the Prime Minister, it would merely add another to the already superfluous number of authorities with which London and Greater London are burdened. We are therefore inclined to deprecate the attitude adopted in this matter by the Council. It must be remembered also, if only for geographical reasons, the problem is one that must be handled by an authority with a wider sphere of action than a committee of the London County Council.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, DECEMBER 3RD.

Civil and Mechanical Engineers' Society.

8 p.m. Meeting at Caxton Hall, Westminster. Paper to be read :—"The Influence of Track upon Railway and Tramway Carriages," by J. Sutherland Warner.

Röntgen Society.

8.15 p.m. Ordinary general meeting at 20 Hanover Square, London. Paper to be read :—"Phenomena Observed in Electrical Currents of Continuous Oscillation," by Dr. Horace Manders.

MONDAY, DECEMBER 7TH.

P. & O. Batti-Wallahs Society.

7.45 p.m. Smoking Concert at Great Eastern Hotel, Liverpool Street, London.

TUESDAY, DECEMBER 8TH.

Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. Meeting at the Municipal School of Technology, Whitworth Street, Manchester. Paper to be read :—"Single-Phase Railways," by P. C. Jones.

Institution of Electrical Engineers: Glasgow Local Section.

8 p.m. Ordinary meeting at 207 Bath Street, Glasgow.

WEDNESDAY, DECEMBER 9TH.

Association of Engineers-in-Charge.

7 p.m. Meeting at St. Bride's Institute, Bride Lane, Fleet Street, London. Paper to be read :—"Coal : Its Composition and Combination," by W. H. Booth.

THURSDAY, DECEMBER 10TH.

Institution of Electrical Engineers.

8 p.m. Meeting at 25 Great George Street, Westminster. Paper to be read :—"Output and Economy Limits of Dynamo Electric Machinery," by J. C. Macfarlane and H. Burge. Time permitting, the following Paper will be read :—"Commercial Electric Heating," by John Roberts.

FRIDAY, DECEMBER 11TH.

Physical Society.

8 p.m. Ordinary meeting.

Telephony in Austria.—Owing to the enormous development of the telephone traffic on the two lines between Vienna and Berlin, two new lines are to be laid. According to the Vienna correspondent of the *Standard*, the Austrian post-office intends to spend a quarter of a million sterling on these and other lines next year. The two new trunk lines are to connect Vienna with Berlin and Frankfort respectively, the latter passing through Munich. The lines at present in use consist of one direct line to Berlin *via* Prague, and one made up of many connections. The new line to Berlin will render communication between Vienna and Hamburg, and even Trieste and Hamburg, easy of accomplishment, so that there will be a direct link between the shipping interests of the Adriatic and the North Sea. In Austria itself a new trunk line is to be built between Vienna and Prague, and local conditions are also to receive consideration. The important manufacturing towns in Bohemia, Moravia, and other districts are also to be connected. In Vienna itself the existing telephone system is to be reorganised, and accommodation for 110,000 subscribers provided, which is more than five times the present number. New main cables will be laid, and new exchanges will be built in various parts of the city.

NEW COMMON BATTERY EXCHANGE AT CARDIFF

By T. Devereux

A NEW common battery exchange is at present in course of construction as an extension of the Cardiff Post Office. Although constructed by the Post Office, it is intended for the use, until 1911, of the

Fig. 1.—Arrangement of Apparatus at Rear of the Sections.

National Telephone Company, whose central exchange in Cardiff has outgrown the capacity of the building in which it is at present located. The new exchange will have a capacity for approximately 10,000 subscribers, and an equipment for 4,600 has been provided at present.

The street cables will be jointed to silk- and cotton-covered cables in the external chamber outside the building, and the latter will then be led to the horizontal side of the main distributing frame, where they will be terminated on porcelain strips fitted with fuses. The main frame is situated in the basement, in the same room as that containing the main frame of the Post Office existing common battery exchange, for hitherto there have been competing telephone systems in Cardiff. A two-position engineer's desk, equipped with the necessary apparatus for testing the lines, is also fixed in this room.

The vertical side of the main distributing frame is fitted with lightning arresters and heat coils, each strip accommodating 120 circuits. The lead-covered silk and cotton-covered cables (each of which accommodates 200 circuits) conveying the lines to the apparatus room are taken up the existing chute on their way to the intermediate distributing frame, which is situated on the first floor. Fig. 2 shows the lay-out of the apparatus room. A lamp cabinet does not form part of the equipment, as the lamp resistances have been dispensed with (see Fig. 4). The 24-volt battery passes through the line relay on to the subscribers' *B* line, and line leakage on the *B* line is shown up by the glowing of the subscriber's calling lamp. A 4-volt tap is not used, and no provision is made for automatically showing up a fault on the *A* line. The line and cut-off relays are wired from the vertical side of the intermediate distributing frame, and are numbered to correspond with the operator's panel numbers.

A large proportion of the lines to be joined to the exchange are rented by unlimited service rate subscribers, and consequently only 2,300 service meters have been provided. These are wired by means of 21-wire cables to 100-tag connection blocks fixed at the top of the vertical side of the intermediate frame.

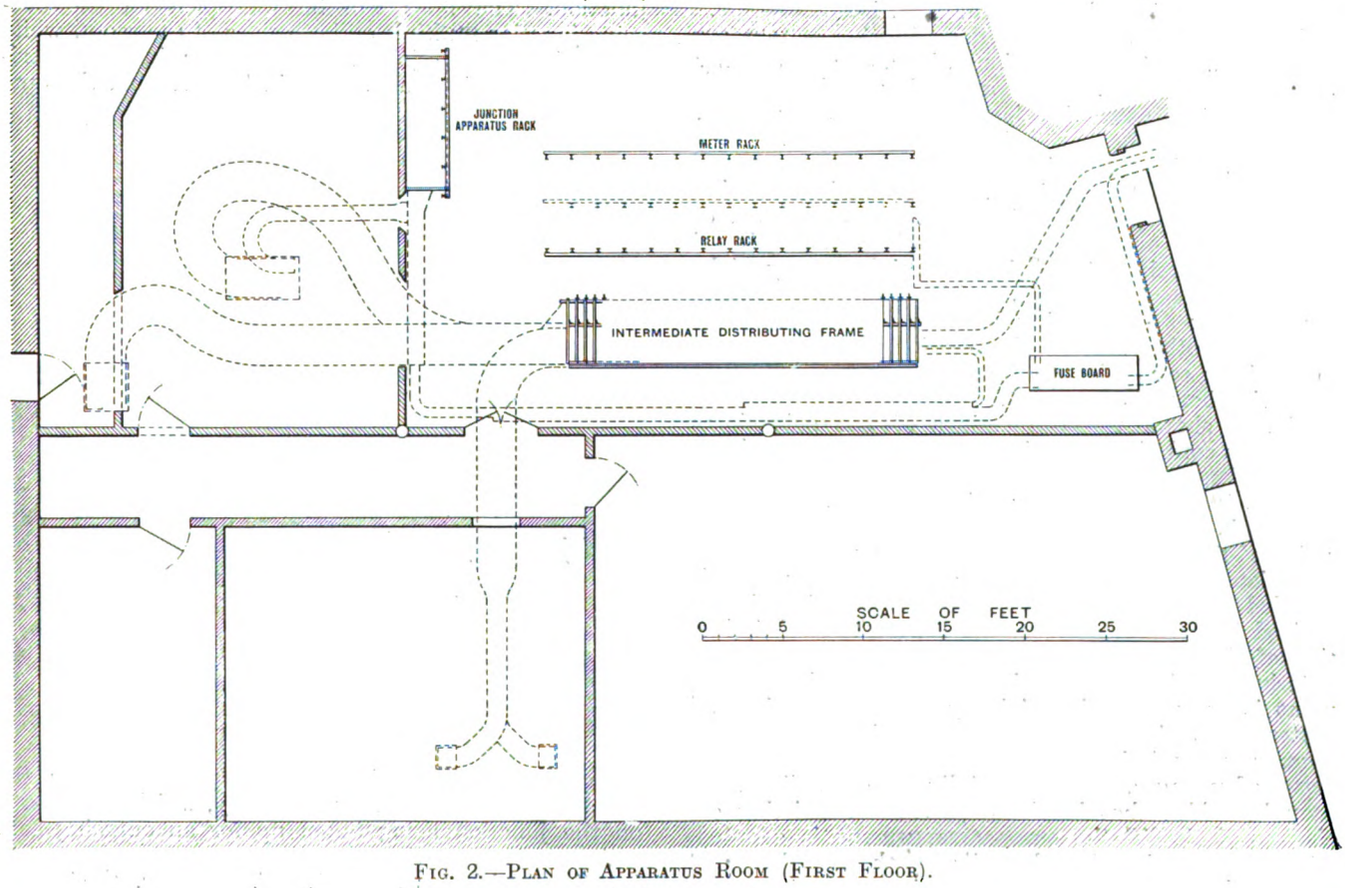

Fig. 2.—Plan of Apparatus Room (First Floor).

Digitized by Google

Single "jumper" wires will be run from the "test" connection of the tags on the horizontal side to these blocks in the cases of the subscriber's circuits requiring the use of meters. On those circuits to which no service meters are connected, the operator's meter will be sensitively adjusted to operate through the cut-off relay. This adjustment is rendered necessary by the fact that under normal conditions the 30-volt battery passing through the operator's meter is insufficient to energise

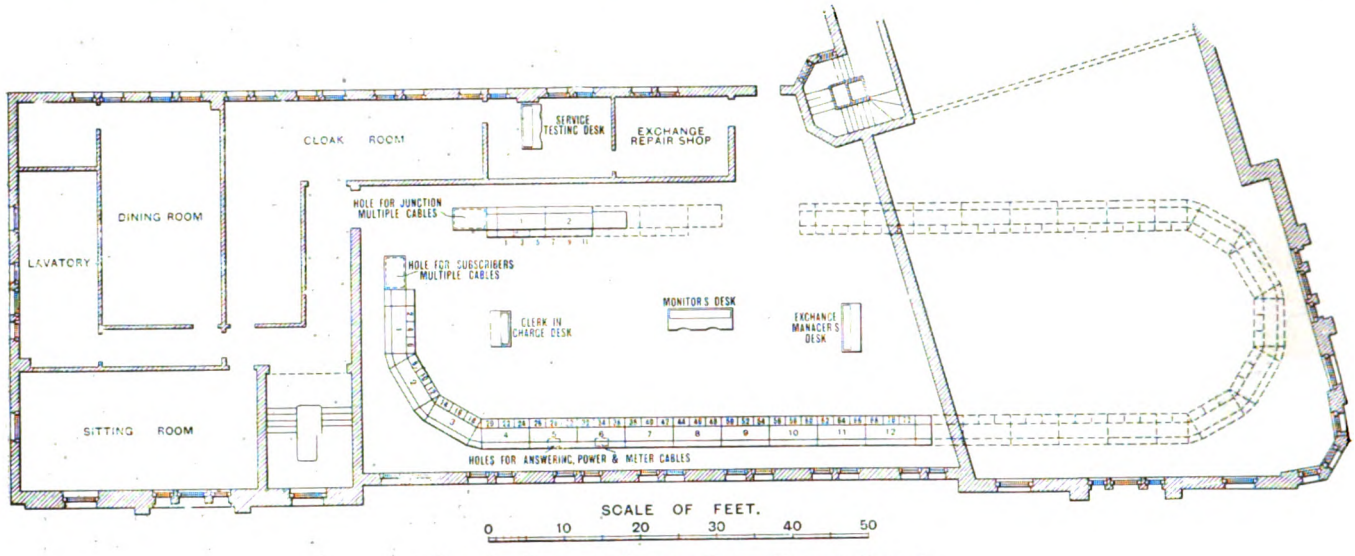

Fig. 3.—Plan of Switch Room (Second Floor).

it until the 40-ohm coil of the service meter has been brought in.

The fuseboard has a capacity for approximately 1,900 fuses, which will be of the bead indicator type.

The subscribers' or *A* positions in the switchroom comprise twelve 9-panel sections with a 3-panel dummy section at each end. The answering positions have capacity for 50 answering jacks and lamps per panel, the present equipment being 40 per panel. Each operator's position contains three panels, and will thus accommodate 120 subscribers. The outgoing junction shelf has capacity for 600 lines, with an equipment of 100 multipled every six panels, and the subscribers' multiple comprises 4,600 lines multipled every eight panels. The last operator's position is fitted as a testing position; no answering jacks or lamps are fitted, although in other respects the position is fully equipped to facilitate conversion to an answering position when the switchboard is extended.

Fig. 5 shows the connections of the subscribers operator's cord circuit, which may be briefly described, as it differs somewhat from the more widely known systems in which repeating coils are used. A steady current is fed out from the battery on to the subscribers' lines through the supervisory relays and retardation coils, and a path for the speech waves is afforded through the condensers, which it will be noticed form a shunt across the coils. The self-induction of the coils prevents the speaking currents from entering the battery. It is found that this arrangement is fully equal in efficiency to the repeating-coil system used by the Western Electric Company as regards transmission; while for reception it possesses some advantages, more especially on short lines. It may be added that in the department's existing exchange at Cardiff the same arrangement is adopted, with the exception that the coils are there each wound to 100 ohms, and that the relay is placed in the *A* or tip side of the plug, and the retardation coil in the *B* or ring side.

On the junction side of the switchroom two 3-position sections, each position to accommodate 27 in-coming junctions, are provided with a two-panel dummy section at each end, and a cable-storing section. The junction sections are wired for 81 trunk junctions, 27 magneto junctions, 42 "two-way" junctions, and 12 junctions in-coming from the department's existing exchange in the same building. These latter are for intercommunication purposes between the subscribers of the two systems. The subscribers' lines and the outgoing junctions are multipled on the *B* positions every six panels. "Busy back" and "Don't answer" signals are provided on the *B* positions, but not on the *A* positions.

Fig. 6 shows the connections of the "two-way" junction. The lines will be multipled on the outgoing junction multiple on both sides of the room, while they will also be joined to the *B* or junction positions for incoming calls. It will be seen that the out-

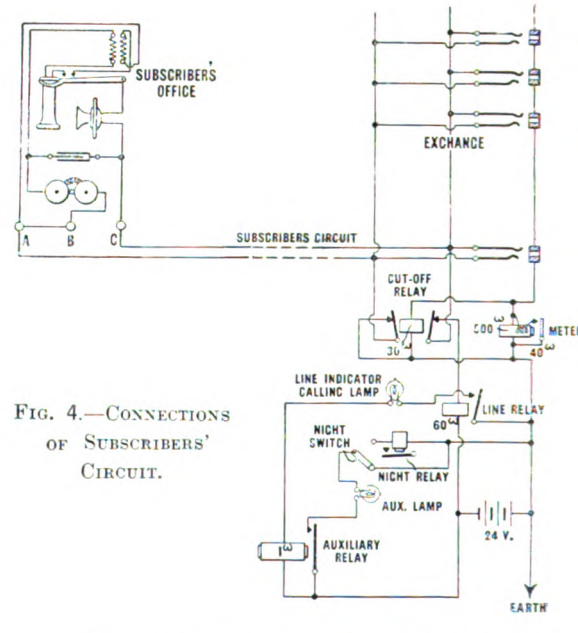

Fig. 4.—Connections of Subscribers' Circuit.

going portion of the circuit is completed through the armatures of the 30-ohm cut-off relay, which is actuated on the junction being taken up for an outgoing call, while at the same time the apparatus on the in-coming junction position is cut out. If, however, the circuit is being taken up for in-coming purposes, the "engaged" test is put on the outgoing junction multiple bush through the 1,000-ohm spool and the left-hand contacts of the 350-ohm relay. The current through the 1,000-ohm spool and the 30-ohm relay is

Digitized by Google

insufficient to actuate the latter, and the normal conditions required for incoming calls are thus retained. Two pairs of supervisory relays and retardation coils are required for each circuit, the relay on the left being energised when the lines are looped through the operators' telephone at the distant exchange and lighting the calling lamp, while the right-hand relay controls the supervisory lamp.

The connections of a junction circuit in-coming from the trunk exchange are shown in Fig. 7. The trunk operator, on inserting a plug in the trunk junction multiple, puts the battery tone test is put on the sleeves of the trunk junction plugs to inform any other operator making the engaged test that the subscriber is connected to a trunk line.

The five-point jack is provided for the insertion of a plug in cases where a subscriber engaged locally consents to take a trunk call, and is arranged to send a flashing signal to the *A* position where the subscriber is at the time connected.

The sections are constructed so far as possible of non-inflammable materials. The skeleton framework is of iron, and Quebec ash is used inside the sections. The fronts of the sections are of polished mahogany, which is backed with uralite. The plug-shelf and the

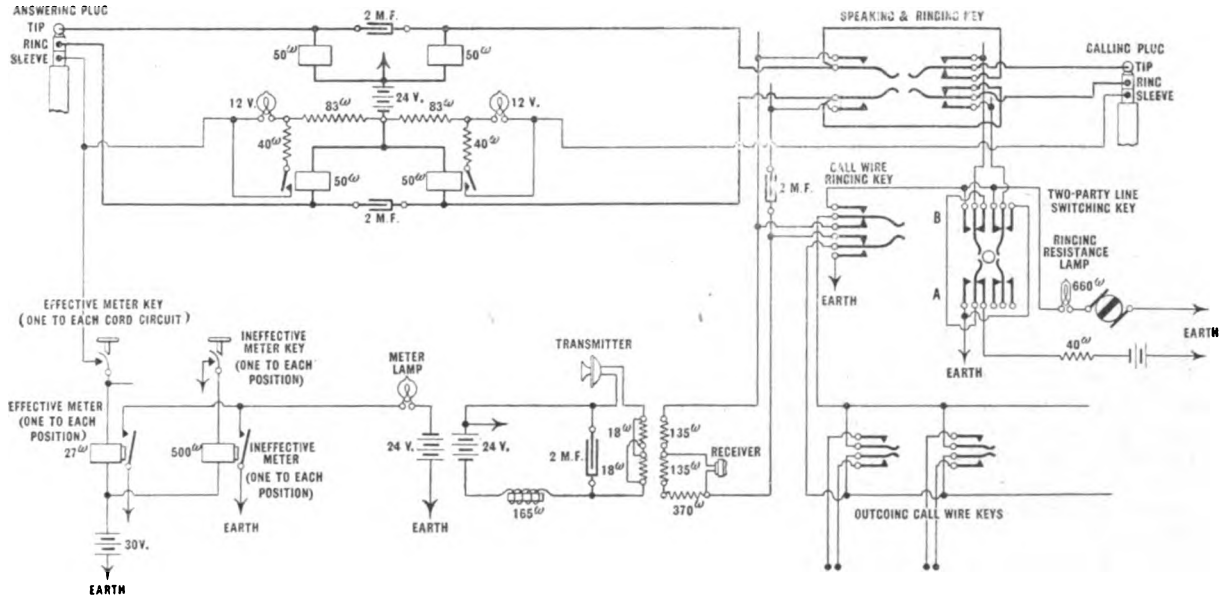

Fig. 5.—Subscribers Operators' Cord Circuit.

on the bush. The current splits equally through a 500-ohm spool at the trunk end and a 500-ohm relay at the junction position. The energising of this relay causes the 12-volt calling lamp to glow, the current also passing through a 40-ohm relay through the armatures of which the line connections pass. At the same time, current from the battery flows from the junction position through the left-hand contacts of a 350-ohm relay, and bridging coils on to the *A* and *B* lines and to earth at the trunk end through the operators' cord-circuit relays, lighting a red lamp on the trunk position. On the junction plug being placed in the subscriber's multiple, a double 83-ohm relay is actuated, and completes the *A* line

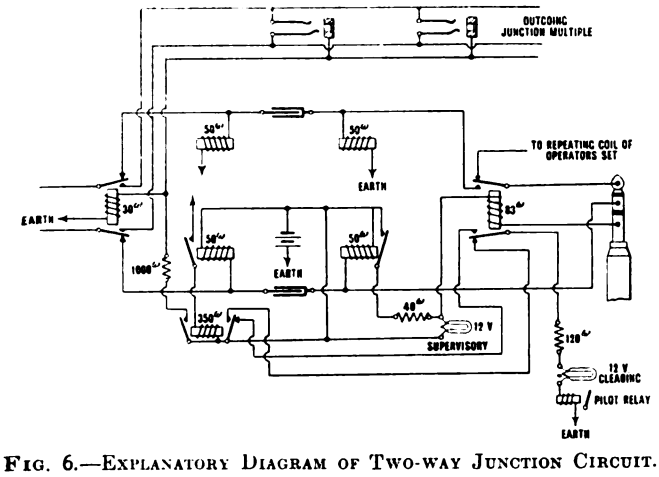

Fig. 6.—Explanatory Diagram of Two-way Junction Circuit.

connection through the top contacts, while at the same time the 12-volt calling lamp is shunted by the 40-ohm relay. When the subscriber replies, a 50-ohm supervisory relay is energised, and a path is provided for battery through the 350-ohm relay, breaking the left-hand contact and the path of the battery to the trunk exchange. The red lamp is thus darkened, intimating to the trunk operator that the subscriber is in attendance. The trunk operator clears to the junction position by breaking the circuit of the 500-ohm relay, and the calling lamp again lights at the junction position owing to the 40-ohm relay which was shunting the lamp being cut out. A special

portion of the key-shelf in which lamps are located is covered with leather, let in flush with the surface of the woodwork. The key-shelf slopes upward in continuation of the plug-shelf. The space above the multiple equipment line is filled in with polished mahogany slabs backed with uralite.

The apparatus associated with the operators' cord circuits is fixed on hinged mounting plates in the lower part of the sections at the rear of the positions, as shown in Fig. 1. The arrangement does not interfere with the changing of faulty cords, which can be effected without removing the wood panels at the front of

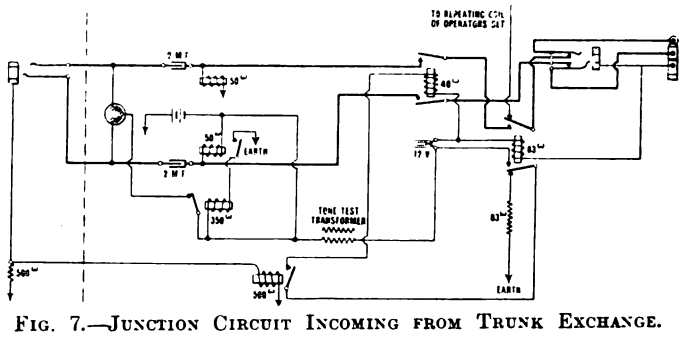

Fig. 7.—Junction Circuit Incoming from Trunk Exchange.

the section. The sections are closed at the rear by means of sliding panels of sheet-iron.

Desks for the chief operator, exchange manager, and monitor (the two latter each with two positions) are provided, the wires to the desks being conveyed in 42-wire lead-covered cables run in wrought-iron pipes laid in the floor. An instruction circuit to the "A" positions, by means of which conversation can be effected with all the operators simultaneously, is wired to the monitor's desk.

When a plug is inserted at the desk, a lamp, provided with a green cap, glows on each of the three operators' positions at

D

Digitized by Google

each section. Each operator, on receiving the glow, depresses a spare call wire key, to which the instruction circuit is wired, and by so doing brings her telephone across the line, and at the same time, by means of two special springs, completes the circuit of a 350-ohm relay and cuts off the lamp. The operator then listens to the instruction required to be given from the desk, the circuit being again normal when the instruction circuit key is released, and the plug withdrawn at the desk.

A service-testing desk is fixed in a separate room adjoining the switchroom, to enable observations to be made in cases where it is required to watch the working of any subscriber's circuit. It is equipped at present with 30 lines.

In addition to the bees-waxing of all the cables, special precautions have been taken to maintain the insulation of the equipment, in view of the adverse atmospheric conditions which obtain in South Wales. On the main distributing frame, the cable forms are lapped with tape, which, with the laced wires, is afterwards coated with shellac varnish. On the horizontal side of the intermediate distributing frame the lead sheathing of the cables is covered with fire-resisting tape, where it is likely to come in contact with laced portions of other cables, and where the cable forms are tied to the framework the latter is first covered with bulldog tape. The whole of the cable forms and lacings in the intermediate distributing frame-room are also coated with shellac varnish. In the switchroom the keyboard cables are first lapped with bulldog tape and afterwards with fire-resisting tape, while the portions of the cables not treated with tape are shellaced. In no case are laced wires allowed to come in contact with the ironwork.

A system of emergency and fire-alarm circuits is also provided. The former consists of an arrangement of keys, electric trumpets, and lamp signals for calling together the male staff in case of emergency, and the fire-alarm circuits include a number of press buttons and alarm bells to be used when it is necessary to warn the whole staff to quit the building.

The exchange will be run from the existing power plant, with the exception that sufficient plates will be added to the two sets of secondary cells, which are at present only partially fitted, to bring them up to their full capacity of 3,060 ampere-hours at the nine-hour discharge rate.

The power plant comprises two motor generators for charging, one of 16 h.p. driven from the Corporation supply at 400 volts, and the other of 7½ h.p., driven from the Department's 105-volt supply. There are two smaller motor generators of 0·18 h.p. for ringing, both driven from the Department's supply, one of them being used for trunk-ringing purposes. There is also a reserve motor generator for ringing, which is driven from the 30-volt meter battery. Separate recording ammeters will be placed in the 24-volt and 30-volt battery leads to the new exchange, so that the amount of current taken to work the exchange may be measured.

An extensive scheme of underground work is being carried out in conjunction with the exchange equipment, cement ducts varying in capacity from 20-way to 3-way being laid along the principal thoroughfares. In the outlying parts of the town distributing poles will be erected, and the cables will be taken to these poles from the duct lines by means of 3-in. cast-iron pipes.

The writer is indebted to the British Insulated & Helsby Cables, Ltd., who have been entrusted with the carrying out of the exchange equipment, for the copies of diagrams, &c., accompanying this article.

A New Australian Engineering Journal.—The first number of a new monthly journal entitled the *Australian Mining and Engineering Review*, which is to hand from Melbourne, contains general notes and articles on the progress of mining and other engineering in Australia, and includes a special electrical section. Comprised in this there is a fully illustrated technical description of the electrical equipment of the Broken Hill Property Co., and an abstract of Mr. C. H. Merz's report on power supply in Victoria.

STREET LIGHTING IN MARYLEBONE

A SPECIAL Committee was appointed some few weeks ago by the Marylebone Borough Council on the recommendation of the Electric Supply Committee to consider a proposal to adopt electric street lighting generally instead of the present incandescent gas lighting. In a note on page 626 of ELECTRICAL ENGINEERING of November 5th we gave some details of the consulting engineer's report, according to which the total cost of electric lighting in those streets in which the mains are already laid would amount to £8,650 per annum; this figure would include the cost of the change over and all other extra charges. The cost of the present gas lighting for the same streets is £8,818 per annum. The report further states that after ten years this annual charge for electric lighting would be reduced to £8,130. The Special Committee will submit a report to the Council at the general meeting this evening, and we shall be able to publish the exact nature of the report and the results of the discussion in our next issue.

By the courtesy of Mr. F. A. Wilkinson, the Electrical Engineer and Manager to the Marylebone Electricity Department, we are able to publish the following particulars of the proposals. The number of lamp-posts in the streets in which the mains are already laid amount to about 2,000. Some have single, some have double, and some triple incandescent gas-burners, and it is proposed to put in two metal filament lamps in series in each lamp, of such candle-power that the light given is the same as, or slightly better than, that given by the present gas-mantles. In some special cases, two or more groups of two lamps in series will be used. The lamp-posts and the lanterns themselves will not be altered. Each lamp will be connected direct to the service mains with the necessary switch and fuses, but meters, of course, will not be used. The men who at present light up and extinguish the gas lamps will be required to switch on and off the electric lamps, as the cost of installing an electric control system—as, for example, that in use in Berlin for controlling the arc lamps (see ELECTRICAL ENGINEERING, November 19th, 1908, page 666), in which a single control conductor only is needed—would be too high. As the times of switching on and off are definite, the consumption of the lamps will be easily estimated. The present station plant is, of course, quite capable of dealing with the increase in the peak load which the above scheme would cause, and the steady load through the dark hours of the night will be a valuable means of improving the load factor.

With regard to the method of payment, it appears that the Lighting Committee will pay to the Electricity Department an annual sum about equal to that which has been paid to the gas company, for which the Electricity Department will have to bear all the capital charges connected with the change over, to maintain the lamps, and to supply the current. Although flame arc lighting is such a prominent feature in Oxford Street, we understand that no alternative proposal for arc lighting of other streets in the district has been considered. In this connection it may be interesting to mention that the cost of the Oxford Street arc lighting with eighty-seven flame arc lamps amounts to somewhat over £1,600 per annum. As the lamps only burn sixteen hours with one pair of carbons, the cost of trimming is somewhat high, and the total cost of carbons at 3d. per pair is also a large item over the whole year.

Underground Telephone and Telegraph Wires in London.—A reply has been received from the Postmaster-General to the London Borough Councils' letter recommending the placing underground of all telephone wires in order to provide work to alleviate the distress among the unemployed. Broadly speaking, the Postmaster-General states that he has no overhead wires at all in Central London. Such light lines as have been erected overhead in the outer and semi-rural districts of the London area could not be placed underground except at excessive cost. The suggestion of the Council does not appear to him to be practicable, but he is pressing forward extensions of the main underground telegraph system of the country which can be rightly claimed as a good and profitable investment.

The Electrochemical and Electrometallurgical Industries in France.—The following information is taken from the report of the British Consul in Lyons. The production of aluminium in France increased from 1,647 tons in 1904 to 3,396 tons in 1906; the total for 1907 is not yet available, but will probably be less than that for 1906. The following companies have established a supply of energy in large quantities for electrochemical purposes:—The Grenoble Power & Light Co., who have power stations at Moutiers, Avignonnet, and Bellegarde; the Central Electric Energy Co., who transmit power generated on the Drac as far as St. Etienne; and the Mediterranean Littoral Electric Energy Co., who supply the whole of the South of France from stations on the Durance. The principal electrochemical products are cynamide and nitrate of lime.

ELECTRICITY SUPPLY AND DOMESTIC HEATING AND COOKING

A PAPER by Mr. W. R. Cooper relating to the use of electricity for domestic heating and cooking purposes was discussed last Thursday at the meeting of the Institution of Electrical Engineers. The author considered the subject as affected by the price at which the supply can be obtained, and incidentally reopened the discussion on systems of charging.

Mr. Cooper remarked at the outset that almost all existing tariffs had discouraged the use of electric energy for domestic power purposes because they were devised primarily for consumers requiring light.

In reviewing existing tariffs, the flat rate, in spite of its simplicity, was dismissed as unsuitable, because the flat rate, to be remunerative for lighting, must be much too high to induce any consumer to consider the problem of electric heating and cooking.

There was no doubt that the maximum demand system, as introduced by Mr. Arthur Wright, was sound in principle, but it was formulated at a time when lighting alone had to be considered. The system was still largely in use, and out of a total of 405 stations it was maintained in about 170.

Nevertheless, it had not been a complete success for the following reasons: (1) Owing to the popular difficulty in understanding the system, it has generally been necessary to give as an alternative a flat rate, having for its value a figure about midway between the limits used for the maximum demand. Thus if energy were supplied at 7d. for the first hour and 2d. thereafter the flat rate might be, say, 4½d. or 5d. The effect of introducing such a flat rate was to rob the maximum demand system of much of its value, because consumers chose the system that was likely to be the cheaper, and the supplier was certain to be left with all the short-hour consumers on a comparatively low flat rate. (2) In the light of recent progress the limit imposed by a maximum demand has proved to be undesirable in domestic supply because it necessarily restricts the use of the supply for other purposes. This point is all the more important now that metallic filament lamps are coming rapidly into use. Such lamps reduce the load and thus also the maximum demand. The consumer will, therefore, hesitate more than ever to connect up even a 500-watt kettle, which alone is equivalent to nearly seventeen 30-watt lamps. (3) One great disadvantage of the maximum demand system is that it does not discriminate between different times of day. It is highly desirable, no doubt, to keep down the load in a house during times of peak load at the station, but there is no object in imposing a maximum demand at other times of day. In fact, the station engineer would welcome such loads, but any progressive spirit in the consumer is hampered by the demand indicator.

He said that the "contract" demand system proposed by Messrs. H. W. Handcock and A. H. Dykes was not suitable for domestic supply on account of the "contract demand," akin to maximum demand, on which it is based.

In order that a domestic power or heating load shall be cultivated, the tariff must have the following characteristics:—It should be simple; it should permit the use of electrical energy for both lighting and power equally; it should exclude two distinct tariffs with duplicate wiring; it should be independent of a maximum demand; it should, nevertheless, discriminate in some way between the lighting and the power load because these loads differ essentially in their total cost of supply.

Fortunately the character of domestic lighting does not vary much during times of peak load. One consumer may run lamps through the night or have dark passages requiring illumination by day, whereas another consumer may use his light merely during the time of heavy load. As far, however, as the capital charges connected essentially with lighting are concerned, we need only consider the characteristic peak load, any more extended use of the light being considered simply as power. The charges peculiar to this peak load must be provided by a special yearly payment in some form or special rate, the rate per unit being otherwise small and uniform. The particular part of the load to which reference is here made is indicated in Fig. 1, which shows the mid-winter load curve of the Richmond (Surrey) generating station. Although there are a number of motors connected to the mains of this station, the load is almost a purely lighting load, and the curve is doubtless characteristic of lighting as distinct from power. It need scarcely be remarked that such a load curve is very far from ideal, but it is typical of many undertakings where industrial developments cannot be expected. From the point of view of tariffs this load may be divided into two parts—the shaded and the unshaded parts in Fig. 1. The shaded part is what is here termed the lighting load, and the unshaded part the power load, although part of the latter no doubt consists of lighting.

Tariffs dependent upon Rateable Value.—The tariff introduced by Mr. F. M. Long at Norwich, and recently adopted at Wrexham, affords a means of providing for these capital charges. The Norwich Corporation make an annual charge of 12 per cent. on the net rateable value of the consumer's premises and a further charge of 1d. per unit. At Wrexham the Council have decided to charge 12½ per cent. on the rateable value and a flat rate of 1¼d. per unit, less a discount of ¼d. Rateable value in itself, however, is by no means a constant quantity, and does not depend merely upon the size of a house. Not only so, but the same size and class of house may vary widely in the extent of the wiring, and materially in the candle-power of the lamps in use.

Tariffs based on Two-rate Meters.—The peak load cannot be conveniently restricted by imposing a maximum demand, because this prevents the demand being exceeded during other times

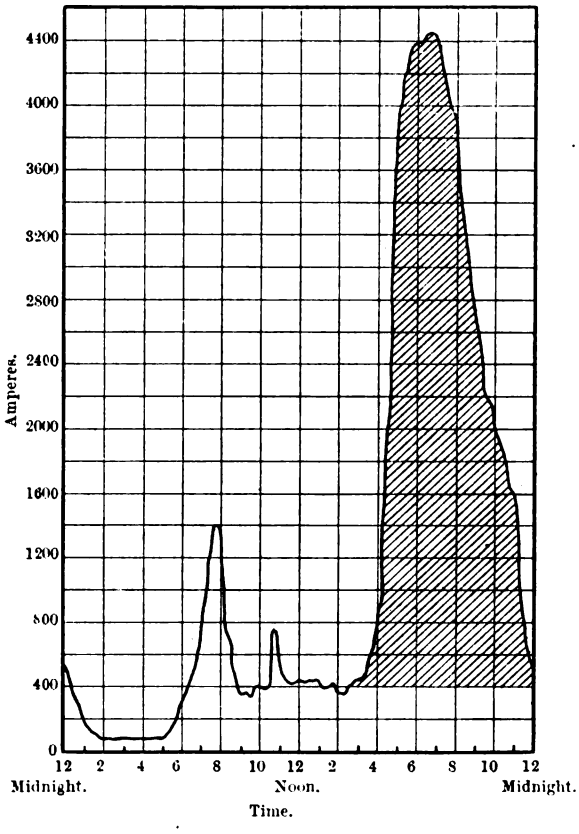

FIG. 1.—MIDWINTER LOAD CURVE OF THE RICHMOND (SURREY) GENERATING STATION, FRIDAY, JANUARY 10TH, 1908.

of day when the load would be acceptable. This objection, however, does not apply to the imposition of a higher price during certain hours of peak load. Difficulties are, however, introduced by the fact that the load curve varies very much according to the time of the year, as shown by the examples in Figs. 1 and 2. The virtue of the system is really its inherent defect. A peak load would certainly be discouraged, but consumers could scarcely be expected to suspend all heating and cooking operations between any particular hours; yet if the consumer indulged in such operations within those hours he would be penalised by the higher price. On the whole, it must be admitted that this system, sometimes referred to as the Kapp tariff, does not provide a satisfactory solution, the more so because it involves the use of two-rate meters, which would necessitate further complication and expense in a branch of the business where simplicity and cheapness should be the characteristics as far as possible.

Tariffs based on the Lamps Installed.—Another basis for a suitable tariff is the equivalent number of 8-c.p. lamps installed. This system has the advantage that the charge has a definite relation to the commodity purchased; it is easily applied, and differentiates between the use of 8-c.p. lamps and 16-c.p. lamps, or between metal filament lamps and low-efficiency carbon

Digitized by Google

lamps. But there are one or two practical difficulties. It will be urged that lamps are liable to be changed; that 8-c.p. lamps may be replaced by 16-c.p. lamps in their renewal, and that low candle-power lamps might be wilfully replaced by high candle-power lamps after an inspection. Possibly it might be desirable to consider lamps in lavatories, and other situations where the use would be very intermittent, as forming a class to themselves, a reduced annual charge being made in such cases. The tariff based on assessment has the one advantage of simplicity, but a tariff based on lamps installed has the further advantage that the consumer benefits if he uses high-efficiency lamps, and pays according to his demand. This kind of tariff

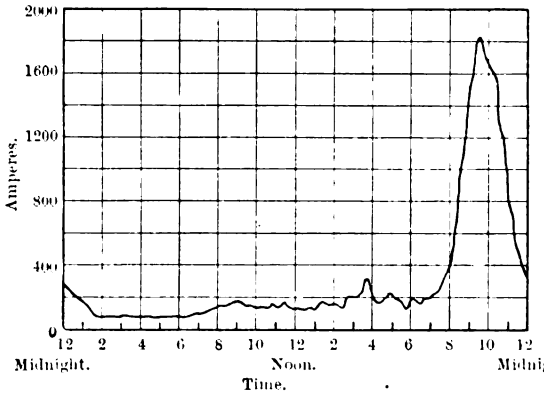

FIG. 2.—MIDSUMMER LOAD CURVE OF THE RICHMOND (SURREY) GENERATING STATION, TUESDAY, JUNE 30TH, 1908.

was at one time tried at Manchester by the late Dr. John Hopkinson, but was abandoned—probably because it was before its time.

The tariffs under discussion, continued the author, practically consist of, or are equivalent to, a lump annual sum for standing charges for lighting, plus a flat rate which must provide the running charges for light and power and any other legitimate charges in regard to the latter. If electric heating and cooking are to be seriously encouraged it is essential that the flat rate part of the tariff should be low. It will be generally admitted that 1d. per unit is a limit above which the public cannot be expected to go, and it is worth while to consider whether a lower limit may not be taken with advantage. In estimating costs in a case of this kind it is always difficult to decide how far one is justified in taking merely the *additional* cost of the units involved as a basis for the tariff.

Estimated costs were then gone into in the Paper for the purpose of showing that the upper and lower limits of the cost to the generating station of supplying domestic power, might be taken as 0·18d. to 0·45d.

This cost does not include any profit, and, therefore, cannot be regarded as giving a satisfactory figure for the charge to the consumer. So long as no additional plant or mains are required to meet the demand for domestic power, this point need not be seriously considered, but if further plant is required (as it certainly would be if such a demand were stimulated), the question of profit becomes important. For this item it is difficult to take definite figures in the general case, but in many cases it will, no doubt, be permissible to take £50 per kilowatt as the cost of *additional* generating plant and mains for domestic power purposes. Assuming the efficiency of distribution to be only 80 per cent., and the load factor to be 25 per cent., then 5 per cent. on this additional capital outlay will be 0·34d. per unit. A profit of 5 per cent. can only be regarded as a minimum, but with an increasing output this figure might be expected to increase to a more satisfactory amount. Thus for the "total cost," including interest on capital, we arrive at 0·77d. per unit as the lower limit and 1·12d. as the upper limit for this class of supply. Although ½d. per unit as the flat rate part of the tariff would leave a small profit under favourable circumstances, it is probable that such a low figure could not be adopted without risk. A charge of 1d. per unit is an upper limit above which the public are not likely to take up domestic power to any serious extent. The intermediate figure of ¾d. per unit includes a considerable profit, and in many cases might be adopted with advantage for consumers taking energy for lighting.

The Economic Aspect of Electric Heating and Cooking.—A small room of 1,500 to 2,000 cub. ft. can be heated by burning, say, ¼ to ⅓ cwt. of coal per day of 12 hours, and at 25s. per ton this would cost 4½d. to 5d. per day. If a radiator were used requiring 1 kw., which is an ordinary figure, the consumption per day would be 12 units if kept on continuously at full rate, or 9 units if used at half-rate for half the time. From this it is apparent that 1d. per unit is not a very encouraging tariff. The electric radiator must depend upon other virtues than its efficiency if it is to become really popular; and the heating of houses on a large scale electrically cannot be expected by this means with electric energy at present prices. Fortunately its virtues are sufficient to make the radiator popular, at least for auxiliary heating, if the charge for energy is reasonably low. For auxiliary heating the radiant, or lamp, form of radiator is certainly preferable because it has a cheerful appearance when in use, its effect is felt at once on switching on, the heat can be directed where required, and the heating elements are replaced very easily. There is no doubt that such radiators have a large field of usefulness before them in small sitting-rooms and bedrooms if electric energy is supplied at 1d., or less, per unit.

The prospect of heating houses entirely by electricity seems somewhat remote. The only method that appears practicable is to heat bodies of water at night, thus forming a kind of thermal storage system. Those who have travelled in cold European countries during the winter will have noticed the large earthenware stoves there in use; these are often heated in the morning by burning quite a small quantity of wood in them, the heat being first absorbed by the stove, and given out during the later parts of the day, thus maintaining a comfortable temperature at a minimum of cost. Similarly bodies of water in different parts of the house might be heated during the night, energy being provided at a much lower rate through a two-rate meter between, say, midnight and 6 a.m.

There is one little electric heating device that could probably be put to much more useful service in this country than at present: and that in the electric flat iron. In America this device has been found very useful for arousing the householder's interest in electric heating and cooking, and once this interest has been aroused the chance of introducing other electrical apparatus is much increased.

A little consideration will show that electrical methods are inadmissible for cooking as a whole unless separate coal-fired plant is installed for the water system. Such plant would be economical, and it is quite possible that this method will come into favour; also that flats will be supplied with hot water from a central service, as in America. In that case the prospects of electric cooking would be much improved. Meanwhile, however, it seems that electrical methods will be used as an auxiliary rather than as a main agent, somewhat in the same way as gas, which likewise suffers through the hot-water difficulty. In competition with this rival, although perhaps not so cheap, electric cooking has some marked advantages which should be borne in mind. Briefly these are as follows:—(1) Cleanliness; (2) ease in regulation; (3) better quality of cooking owing to greater certainty of results, and in certain operations, such as grilling, better than gas because of freedom

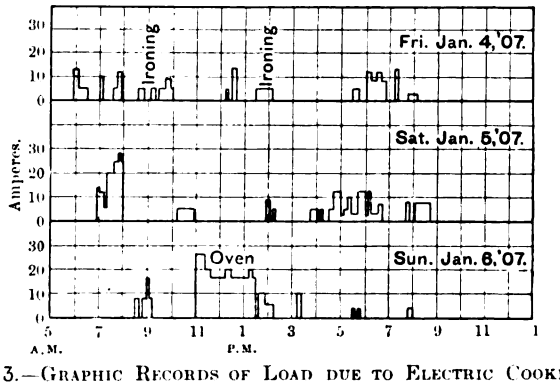

FIG. 3.—GRAPHIC RECORDS OF LOAD DUE TO ELECTRIC COOKING, BY J. R. CRAVATH.

from any taint; (4) very little smell; (5) coolness, thus rendering the method very advantageous in summer; (6) great adaptability, so that cooking need not be entirely restricted to the kitchen.

When we come to the important question of the relative cost of electric cooking we find that very little information is available. Practically nothing on this subject appears to have been done in this country. In America more keenness has been shown.

Mr. J. R. Cravath kept careful records of electric cooking in his home at Chicago during one month. Hot water was supplied otherwise. From the results it appears that if the price of electricity is more than 1½d. per unit it is more expensive than gas at 4s. 2d. The load diagrams in Fig. 3, obtained by

Digitized by Google

a recording instrument during the month referred to, are of interest as showing the variation of the load from day to day, and they indicate that a good diversity factor may be expected from electric cooking.

At the Convention of the Canadian Electrical Association last year, and again at the Convention of the National Electric Light Association, the opinion was expressed that the consumption per person per meal may be safely taken at 300 watt-hours, and this figure is borne out by the records mentioned above.

The General Electric Company have found experimentally the cost of cooking a good plain dinner for eight persons electrically to be 4½ units.

Messrs. Isenthal & Co. have kindly supplied the figures of comparative experiments on the cost of electric cooking for three persons carried out in Switzerland over a period of three months, which show that the cost per day with energy at 1d. per unit would be from 2·19d. to 2·24d.

The cost of cooking with paraffin oil for the same household averaged 3·3d. per day (1½ quarts of oil), thus showing an advantage in favour of electricity. For a larger number of persons the cost would not, of course, be proportionately heavy.

We thus get some idea of the consumption, and can now arrive approximately at a suitable price from the consumer's point of view. Returning to the case of a household of eight persons to which reference has already been made, the consumption per meal would be 2·4 units, or, assuming three meals per day, 7·2 units per day; or allowing for contingencies, say 8 units per day, which is probably on the high side for eight persons. This consumption, which does not provide hot water for general purposes, must be compared with the cost previously mentioned of cooking with coal, including the heating of water, at a cost of 9½d. per day. It is thus apparent that a charge of 1d. per unit will permit electric cooking to be adopted to a considerable extent in competition with coal, though a lower charge would certainly be desirable, more particularly with gas in the field. Possibly electricity at 1d. might be taken as being equivalent to gas at 3s.

Considering the ease with which electric energy is converted into heat, it is a little curious that the apparatus for electric heating and cooking should be so expensive. This high first cost is certainly retarding development; but, on the other hand, cheap apparatus, if inferior, is still more harmful. A bad effect has also been produced at times by placing unsuitable apparatus on the market. Manufacturers would do well to retain the services of an experienced cook rather than to gain experience at the expense of their customers. Thus only harm can be done by selling grills which burn the meat instead of grilling it, and give rise to objectionable smell; or toasters which convert bread into pudding instead of toast. One such unsuitable piece of apparatus (and they are common enough) is sufficient to make a prospective customer condemn the whole system. A somewhat high figure for maintenance is also a difficulty at the present time, though doubtless this will diminish with time.

In regard to efficiency, Mr. C. H. Archer, of the General Electric Company, has kindly placed the following experimental results at the author's disposal. The efficiency of a self-contained heater vessel for boiling water varies from 87 to 92 per cent. If a hot plate, or separate heater, is used the efficiency is generally much reduced, the extent of the reduction depending on the state of the surface of the vessel and the goodness of the contact between the vessel and the hot plate. Thus if the bottom of the vessel is practically perfectly flat, and it is *clamped to the hot plate*, the efficiency is 92 per cent. of the above, or the resulting efficiency is 84½ per cent. But if the vessel is merely placed on the hot plate the efficiency may drop down to 35 per cent. of the 92 per cent. first mentioned, or a resulting efficiency of only 32 per cent. Suppliers of electricity would do well to hire out the simpler forms of apparatus for both heating and cooking more generally than at present, on the lines of the gas companies, for it must not be forgotten that successful apparatus is the best possible advertisement of the supplier, and will in many cases lead to further trial. The use of electrical domestic apparatus of all kinds is certain to extend largely in the near future.

A field that is more easily attacked than the private house is the hotel or the restaurant. Hotels are beginning to realise that electric cooking has passed the experimental stage. A large grill taking 3 kw. per compartment is in use at the Waldorf Astoria Hotel in New York; London hotels also have the question under consideration. Restaurants are finding the advantage of the electric grill, partly because of the convenience and good results, and partly because it interests the customer. An electric grill and other apparatus is at present being used experimentally by the James Fleming Restaurants in London with satisfactory results, and plant for cooking is also being given a trial at one of Messrs. Slater's Restaurants, at Messrs. D. H. Evans & Co., and elsewhere. Mr. Fleming has carried out a short test (3 hours) between his electric grill and a gas grill of about the same size, and he has kindly supplied the following approximate figures. The electric grill consumed fully 3 units, and the gas grill required 75 cub. ft. of gas; thus with electricity at 1⅛d. and gas at 2s. 10d., the electric grill cost about 3½d. as compared with 2½d. for the gas grill. With a 1d. rate, which is more usual, the figures would be roughly as 3d. to 2½d. The time taken to cook a chop with either grill was the same, but Mr. Fleming is inclined to think that, were both the grills worked at their full capacity, the better distribution of heat in the electric grill would give it some advantage over gas.

DISCUSSION.

Mr. C. P. Sparks (Engineer-in-Chief, County of London Electric Supply Co.), who opened the discussion, said he was not an advocate of the maximum demand system, nor of that employing two-rate meters. The use of two meters and two circuits was the standard system at present, and it was meeting the difficulty to some extent. Systems of making a charge based upon the wattage of the lamps, as suggested by the author, had been tried before, but difficulties had been encountered in regard to the quarterly inspections, not only on account of the time and cost involved, but also due to the aversion of householders to the servants of public bodies, such as electric supply companies, entering their premises for such purposes. In his opinion, the slow growth of the heating and cooking portion of the electric supply business was not so much due to the tariffs as the apparatus. It was the heavy capital outlay that had to be met either by the consumer or the supply company that was really the drawback, and he very much regretted to see the very low efficiencies given in the paper of that class of apparatus which he had hoped would prove a solution of the question, viz., the hot plate or separate heater. If they could find a separate method of heating so that only a small investment was necessary in a hot plate, or separate heater, which would allow all the ordinary culinary appliances to be used, then he believed they would be able to go forward. He regretted, therefore, to see that an efficiency of only 35 per cent. could, under normal circumstances, be looked for. The question of apparatus, therefore, in his opinion, was of far greater importance than any of the tariffs put forward in the Paper.

Mr. A. M. Taylor (Chief Assistant Electrical Engineer, Birmingham Corporation) sent in a written communication, which Mr. J. F. C. Snell read.

In this communication Mr. Taylor confined his remarks mainly to the question of dealing with peak loads, such as that shown in the curve in Fig. 1 of the Paper, and argued that the use of accumulators instead of additional plant would obviate the necessity for any annual fixed charge to the consumer and in some cases the happy ideal of a common flat rate for both light and power might be reached. He considered the author's estimated costs altogether too optimistic.

Mr. J. F. C. Snell was of the opinion that a simple tariff system was the thing to be aimed at, in addition to a simple system of wiring and simplicity in the design of electric heating and cooking apparatus. He agreed, however, that it was not so much a question of tariffs at the present moment as the first cost of the apparatus itself. The greater simplicity and design of gas cooking and heating apparatus was most striking, and he did not know that a complicated design need be an inherent part of an electrical cooker or heater. In fact, he believed that the ingenuity of the electrical engineer would overcome this defect. So far, there had been a lamentable lack of attention to the whole question. He did not agree with the author's figures for costs; apparently no allowance had been made for redemption of capital. In fixing a tariff, the whole of the costs of production must be taken into account. To base a tariff on running costs alone was simply to head straight for destruction. A great mistake was made in many cases in trying to sell energy for power purposes as a by-product, and he hoped the heresy of attempting to base charges for heating and cooking upon running costs alone would not be entertained by the members of the Institution.

Mr. H. W. Handcock (Messrs. Handcock and Dykes) agreed with the last remark of Mr. Snell. The best system, in his view, was a contract demand system, the whole object of which was to charge the consumer in proportion to the actual outlay that he has cost the station, and if the load due to heating was to be greater than the load due to lighting, then the maximum demand in that case should be based on the heating and not on the lighting load. The present results from heating and cooking were disappointing, and before it would become universal, the initial cost of the apparatus must be reduced and the efficiency improved. Mr. Wilkinson, of Harrogate, was introducing a system by which the consumer might instal any number of lamps, and a fixed charge for an unlimited consumption of energy was made according to the number of lamps installed, so that no meter was required. Free wiring, he

Digitized by Google

thought, must form part of any system which was to popularise electricity for heating and cooking. Once this was done, they were increasing still further the ratio between running costs and the costs due to interest and depreciation, and, finally, they came to a point when it did not matter so much so long as they restricted the consumer to the hours of darkness, whether he burned his lamp for long hours or short hours. Following on these lines, a system was to be introduced at Egham. The supply authority supplied current from dusk to dawn, they wired the premises and charged a fixed sum per annum, no meter being put in. All the consumer had to do was to supply the lamps. Having gone very carefully into the matter, they had come to the conclusion that they could name a sum that would leave a very handsome return to the undertaking and at the same time enable the consumer to get light at less than the present cost of gas.

Mr. E. W. Cowan (Key Engineering Co.) said he was unable to accept the view put forward by the author and by many other engineers that the price of electricity supply should be fixed according to the cost of production. In his opinion, the price should be according to the commercial value of the use of the energy, in the same way that shipping and railway companies varied their tariffs according to the nature of the goods they carried. He had only that week wanted a rate for a port in Africa, and the shipping authorities told him that the freight they would quote depended absolutely upon the contents of the case. Again, why did we have to pay a rate 50 per cent. higher for a case of brass castings from Manchester to London than for a case of iron castings. In this, of course, he came into collision with Mr. Snell and others; but his opinion was that, in considering this matter, they could entirely disregard any question of equity as between one class of consumer and another, although not between individual consumers. For instance, in the case of two consumers, one for lighting and one for power, from the ethical point of view it had nothing to do with the question whether one was charged, with reference to the cost of production, a lower price than the other. In fixing such a tariff, provision must be made for the future, otherwise, as Mr. Snell had pointed out, in trying to sell power as a by-product—which it really was not—they would land themselves in financial disaster. He felt convinced that if station engineers would look at the problem from this point of view, they would secure the domestic power consumer to a much greater extent than had been the case hitherto. They would have to run some risks, and have some trouble, but he thought it was worth while.

Colonel R. E. Crompton said he had some difficulty in following some of the speakers, including the author, without knowing what was in their minds. Were they thinking of the ideal tariffs which might be produced in the future if there were no Board of Trade or no London County Council, or even such things as Committees of Parliament? But as there was not much chance of such a state of things, we must consider matters as they were now, and consider how far their masters, the Board of Trade, for instance, would allow them to go. As a matter of fact, he thought they knew pretty well the length of their rope. It was, that however they shaped their tariffs, they could not go beyond 8d. per unit, and it could only be in most exceptional circumstances, such, for instance, as a millionaire, who only used his house one day in the year, and then had it lighted from basement to attic, that they could make this charge. He rather agreed with the author that double wiring must be avoided; certainly in the West End of London it was the great bar to the use of electricity for cooking and heating. Probably the easiest way of working was with a two-rate meter, the disadvantages of which he did not think were sufficient to put it out of court. He had been using such a meter experimentally himself for years, and although he was not altogether satisfied, yet he had come to the conclusion that by it they could charge 8d. for the very short period of maximum demand in the middle of the peak, and come down to 1d. for the remainder of the twenty-four hours, and work on single circuits. He had been one of the pioneers of electric heating, and his firm had spent a lot of money in this direction, and the reason they gave it up was on account of apparatus being continually ruined by the carelessness of servants, who would allow a kettle to boil dry, which was followed by great overheating. This was an aspect of the question, however, in which considerable improvement had taken place recently. Mr. Cooper had left out one very valuable use of electricity, namely, the production of cold, and there was room for a simple invention for producing cold by electricity in a compact apparatus, which would be useful in this country, as well as in countries like India.

Mr. W. R. Rawlings, after commenting upon the somewhat remarkable fact that this was a second time within six months that a Paper of interest to electrical contractors had been read before the Institution, said he was gratified to learn from Colonel Crompton that he was not in favour of double wiring. As a matter of fact, upon the Kensington and Knightsbridge Co.'s system there were three methods of taking services into the house, namely, one for heating and cooking, one for cellars and basements, and one for the general house lighting, which was, in a fourth degree, subject to certain rebates. Therefore, if they could get rid of this quadruple method, it would be a very satisfactory thing. He disagreed with the author's suggestion that a tariff should be enforced, based upon the total wattage of the lamps installed divided by 30 to give the equivalent number of 8 c.p. 30 watt lamps. The author stated that this system had the advantage that the charge had a definite relation to the commodity purchased, but he doubted this, and compared the case of a grocer's shop, for instance, in which 30 lamps were always being used, and a private house with 100 lamps installed, but only 30 at the most being used at one time. He agreed with Mr. Sparks's views upon the question of quarterly inspections, and mentioned that, as a rule, in the West End, there was generally some excuse why a man could not be admitted into the house, no matter what time of the day he went. Further, he thought that unless a man carried a 20-round ladder with him, he would find it impossible to check the lamps owing to the positions in which they were placed. He also strongly protested against the man making inspections, adjusting switches, &c.; as an electrical contractor, he claimed that to be his work. The author had stated that this kind of tariff had been tried at Manchester by the late Dr. J. Hopkinson, and abandoned probably because it was before its time. He certainly thought it was still before its time. He was further of the opinion that the system would discourage wiring, and drew a picture of householders taking out lamps wholesale, whereas under present conditions they were installed as a matter of convenience and not so much for continual use. In fact, he had been informed by one consumer that he would certainly do this. Summing up, Mr. Rawlings thought that the adoption of such a tariff would do a great deal of injury to contractors, supply companies, and manufacturers alike.

Mr. A. P. Trotter (Electrical Adviser to the Board of Trade), in reference to the remarks of Colonel Crompton concerning the Board of Trade, said that it would be perfectly legal to charge a tariff of so much per annum based upon a man's income tax, divided by the square root of the number of his waistcoat buttons if the supply authorities so wished, but the only restriction which the Board of Trade put upon it was that it must not exceed 8d., and that it must not be refused to anyone else who asked for it under the same circumstances. With these provisos, he was not aware that there was any objection to any tariff. He had nothing further to add, with the exception of this one remark: he was not a commercial man, but he did agree that the price of a thing was what it would fetch.

The President having asked any other members who wished to speak to send in their remarks for inclusion in the Journal,

Mr. Cooper briefly replied, and will deal further with the discussion in writing. He said he must continue to disagree with Mr. Sparks as to the double wiring system, for he was sure that consumers would not go in for the duplication and cost and trouble involved. He had two meters in his own house, but even that was no inducement to make him go in for electric heating or cooking. The speakers who dealt with the difficulty attending quarterly inspections rather overlooked the fact that in pushing electrical heating and cooking, they wanted to deal with existing consumers. They need not worry so much about those West End consumers where is was always inconvenient for the man to be allowed in, but it was worth while to take the matter up with the smaller consumers, and he did not think the difficulty was so serious as it appeared. He agreed that the capital outlay upon heating and cooking apparatus was a difficulty, but if they had unsuitable tariffs, they could go on making the apparatus cheaper and cheaper, but they would not get them installed. Mr. Taylor and some other speakers had disagreed with the costs which he had given. It was always easy to disagree with estimated costs, and he would like to ask one question in this connection. The upper limit he had given was something over 1d.; Mr. Taylor suggested that this should be the lower limit. If that was really so, why were a considerable number of station engineers already supplying at 1d.? Surely they ought not to do so. He agreed with Mr. Snell that there was a certain amount of risk in going on running costs alone, but if they did not take any risks, they would never cultivate a demand; it was a risk which had been taken with regard to power, and he did not think it was so serious in this case. He thought Mr. Wilkinson's tariff would lead to a good deal of difficulty, and this was a point that must be borne in mind. He found it a little difficult to follow Mr. Cowan's idea of a tariff. With regard to Mr. Rawlings's remarks concerning the charge per lamp per annum, he did not wish to fix any particular sum.

Mr. Rawlings: It is not the figure, but the principle that I object to.

Mr. Cooper, continuing, said that he had dealt purely with domestic houses in the Paper, and therefore the other points raised by Mr. Rawlings in his comparison of a grocer's shop and a private house did not apply. He did not think the question of the inspector dealing with switches was so serious as Mr. Rawlings had made out, and the same remark applied to the suggested restrictions in wiring as the outcome of his system.

The President, in proposing a vote of thanks to Mr. Cooper for his Paper, thought the discussion had brought them a little further towards the elimination of the maximum demand

Digitized by Google

system. He thought a clearer recognition that the peak load could not definitely be restricted by imposing a maximum demand would carry them a little bit further towards simplicity of methods of charging. Personally, he believed we should eventually come to a flat rate both for light and power, and not differentiate at all. This would take some years, but he believed it was what we should come to, as it was what everyone else did. A grocer charged so much a pound for his sugar, and did not vary the price according to whether the shop was full of people when the customer called, or whether the customer came when the shop was first opened.

The following written communication was received from Mr. F. A. Wilkinson (Electrical Engineer and Manager, Marylebone) :—At Marylebone we have always recognised the truth of the contention that the future of electricity supply in a district mainly residential lies in development of the domestic power load, and for two years we have been actively pushing this class of business. At the outset it was found that prejudice was very hard to overcome, but recent results in the direction of heating have been most encouraging, and there appears no doubt that the next two or three years will witness considerable extension in the use of radiators. We make a practice, where required, of lending these to consumers for a few days free of charge, and this year, of the many we have put out in this way we have not had one returned. In 2½ years the number of radiators connected has risen from 281 to approximately 600, and we can see very many more ahead. The special circuit difficulty has, of course, been experienced, but it has now been very effectively met by the use of plug submeters rented at 1s. per quarter. Despite the fact that our pressure of supply has been changed from 100 to 240 volts, and that, therefore, the majority of the wiring in the borough is ample in copper, we have met with several cases where a radiator or cookery range would have overloaded the wiring, and this certainly constitutes a difficulty which it is beyond the power of tariffs to remedy.

As regards cooking, results are not so satisfactory, and this appears to be attributable to the high cost of apparatus, prejudice (principally of servants), and the entire ignorance of the average consumer in the very elements of the subject. It will clearly be necessary to do a vast amount of educational work before anything like good progress is made, and in this, as Mr. Cooper says, we are handicapped by the meagreness of comparative data of cost. It has been our experience that manufacturers of electrical, gas, and coal cooking apparatus cannot supply and substantiate any definite practical figures, and the chefs of various restaurants that we have approached appear to have only the haziest of ideas on the subject of costs. It is in consequence of this that wherever possible we are instituting comparative tests under practical conditions, but we find it by no means an easy task to persuade suitable firms or persons to allow us to experiment. Mr. Fleming, of Fleming's Restaurants, Ltd., very kindly gave us every possible assistance, with results that Mr. Cooper has mentioned. The grill used in this test has in many ways been brought to special notice, and the reliable comparison the test affords should be of value. There is no doubt that Mr. Fleming is correct in saying that at full capacity the electric grill would be cheaper than gas, and from an intimate practical knowledge of it I have no hesitation in saying that such a grill split up into a number of sections, instead of only two, would at 1d. per unit be cheaper than the gas grill against which it was tested. Electric ovens, as comparatively large consumers of current, are of particular interest, and the following details of a test carried out for two weeks under practical conditions in a large restaurant will perhaps be useful.

Results obtained with Large Electric Oven in Actual Practice.

Test.	Article cooked.	Weight, lbs.	Time to cook, hrs.	Time to cook, mins.	Units consumed.	Units per lb. of meat.	Remarks.

When working at its full capacity, so far as we have been able to ascertain, the cost at 1d. per unit is certainly not above that of gas. The nearest comparison we were able to make was with a large and efficient gas oven of first class manufacture. This consumed 400 cubic feet of gas per hour, at a cost of 1s. 2d., and had a capacity of 500 lbs. of meat. Taking the capacity of the electric oven at 80 lbs., the cost of cooking is practically the same. We have lent out a considerable amount of cooking apparatus free on trial, and are continuing to do so, as we recognise that this is at present the best means of popularising it. In all but a few cases we have met with opposition from chefs and cooks, and this constitutes one of our chief difficulties. Mr. Cooper rightly lays emphasis upon the bad impression that inefficient or unsuitable cooking apparatus produces. I have found this borne out in several cases, and a bad impression is most difficult to eradicate. Manufacturers are of course well aware of this, and there is no doubt they are improving their goods every day; still, there are one or two points in the average piece of apparatus to which, as a user, I may perhaps be allowed to draw attention. Taking ovens, in the majority on the market, the loss of heat by radiation is very large, and the usual lagging arrangements are entirely inadequate. Consumers object to this radiated heat, and in some cases in our experience it has been sufficient to turn the scale against us. A first class gas oven is in this direction far ahead of most, if not all, of its electrical competitors. Bad heat distribution in the oven is another point upon which we have received complaints, and inaccessibility and neglect of small details which enhance convenience have also been mentioned. In many similar directions, there is distinctly room for improvements that will cheapen and encourage electric cooking. We must, however, bear in mind that the same may be said of gas and coal apparatus, which in many instances is obviously capable of great improvement, and there appears every likelihood that the cost of gas cooking would be materially reduced by means of more efficient apparatus were there any real competition. The fireless cooker, so popular in Sweden, has never been exploited in this country. An American writer states that the cost of electric cooking may be reduced 50 per cent. by means of this principle; surely it is worth while to investigate it. With regard to the future of electric cooking, beyond the question of tariff, it seems to me that the amount of publicity necessary for a quick realisation of our aims cannot adequately be attained on the usual lines of each supply authority, contractor, and manufacturer acting independently, and in too many cases not acting at all.

To popularise electric heating in a reasonable time some concentrated effort calculated to awaken all classes to its possibilities and give it the widest publicity is necessary, and this for very obvious monetary and other reasons can only be attained by some comprehensive form of co-operation.

Secretaryship of the I.E.E.—Mr. G. C. Lloyd, the secretary of the Institution of Electrical Engineers, has been appointed secretary of the Iron and Steel Institute, in succession to the late Mr. Bennett H. Brough. It will be remembered that Mr. Lloyd was assistant to Mr. Brough when, in 1904, he was appointed to his present position. Mr. Lloyd served his apprenticeship with Messrs. Robert Stevenson & Co., marine and locomotive engineers, of Newcastle-on-Tyne, and in 1884 commenced his career as a marine engineer, which lasted for a number of years, during which he made many trips abroad, including Brazil, River Plate, West Indies, Philippine Islands, and the Straits Settlements. Having spent a number of years in constructional work at home, he was appointed assistant secretary to the Iron and Steel Institute in 1901, as mentioned above.

Progress of Domestic Heating in Marylebone.—In spite of the rather general pessimistic feeling with regard to electric heating, and the by no means low power rates in vogue in the borough of Marylebone, considerable progress has been made in the last few months in the sale of electric radiators. As Mr. F. A. Wilkinson, the Borough Electric Engineer, mentioned in his contribution to the discussion on Mr. Cooper's Institution Paper, the total number of radiators in use in Marylebone now exceeds 600. The net increase in the kilowatts connected in the form of radiators and heating appliances from April 1st last up to the end of November was 265 kw.; the corresponding figure at the same time last year was 195 kw., and between April 1st and Nov. 30th, 1906, about 130 kw. was connected. The effect of circularising the consumers is well shown by means of the following comparison :—In the two months, October and November, 1906, 30 radiators were connected, but in the same two months of the following year the net increase in the number connected was 110. In most cases plug meters are used. The difficulty with the tariff is got over as follows :—The maximum demand of the radiators is assumed at a certain figure, and from the reading of the plug meters the charge is made on the basis of the Marylebone power rate of 2d. and 1d. The plug meter readings are subtracted from the main meter reading, and the assumed maximum demand of the radiators is subtracted from the main demand meter in order to calculate the charge for lighting. This method has proved successful where one or at most two radiators are in use, as it may be assumed that both are used at once sometimes. Where more than two radiators are used, the consumption must be metered separately by means of a separate heating circuit. This latter is also necessary for another reason—namely, the fact that the house wiring, as a general rule, is not sufficient to carry the extra load.

THE PROPOSED TAX ON ELECTRICITY IN GERMANY

THE opposition to the proposals of the German Government to impose a tax on electricity, gas, and illuminating apparatus is now being organised. A committee, consisting of representatives of the various branches of the electrical and gas industries and representatives of the consumers, has been formed under the auspices of the Berlin Chamber of Commerce to offer organised opposition to the Bill which will be dealt with by the Reichstag this session. According to the *Elektrotechnischer Anzeiger* the committee is constituted as follows:—Dr. E. Rathenau (A.E.G., Berlin), Prof. Budde (Siemens and Halske, A.-G.), Dr. Linde (Director of the Verein Deutscher Ingenieure), Dr. Körting (Verein Deutscher Gas- und Wasserfachmänner), Dr. von Borscht (Mayor of Munich), Dr. von Mortius and Dr. Wenzel (Society of the German Chemical Industry), Herr G. Dettmar (General Secretary of the Verband Deutscher Elektrotechniker), Prof. Dr. Kallmann (City Electrical Engineer, Berlin), Dr. Fasolt (Wirtschaftlicher Verein der Deutschen Elektrotechnik), &c. The business of the committee will be conducted by Dr. H. Lux and Dr. Bürner.

In a long article in the *Electrotechnischer Anzeiger*, Dr. Fasolt criticises the statements made in the explanatory memorandum published with Bill, an abstract of which was given on page 677 of ELECTRICAL ENGINEERING of November 19th. He first objects to the argument employed in the memorandum, that the industries affected by the proposed taxation will quickly throw off the retarding influence of the tax by means of improvements in the methods of utilising power for industrial purposes and other technical developments, and then points out that, although the total figure of 30 million marks (approximately £1,500,000) for the revenue from electrical sources only may be taken as correct, the costs of administration have been considerably under-estimated. With regard to the way in which this load will be distributed among the different kinds of consumers, he mentions the figures recently published by a German electrical association, which show that the electrical energy consumed for illuminating purposes is distributed as follows:—Private houses, 22·2 per cent.; shops and other trade premises, 22·4 per cent.; workshops, factories, banks, and offices, 16·7 per cent.; hotels, restaurants, and theatres, 18·5 per cent.; public buildings, 10·3 per cent.; public street lighting, 5·4 per cent.; hospitals and asylums, 3·7 per cent.; and sundry consumers, 0·8 per cent. These statistics show, says Dr. Fasolt, that the tax will not be a tax on a "luxury" of the well-to-do classes, but will affect all classes. The tax on energy for power purposes will also be felt very severely by the working classes, as, according to the statistics published, a large number of small motors are used by artisans, carpenters, bakers, &c., in Germany; indeed, it is estimated that about 60 per cent. of the energy delivered by public central stations for power purposes is used by small trade consumers.

With reference to the tax on illuminating apparatus, Dr. Fasolt points out the way in which the carbon filament lamp will be handicapped in its struggle against the metal filament lamp, even in the case of low current charges. As the tax depends on the watt-consumption of the lamp, a 32 c.p. carbon filament lamp will be taxed to the amount of 30 pfennigs, or nearly 60 per cent. of the market price; while a metal filament lamp of the same candle-power will be taxed to the amount of only 20 pfennigs, or 9 per cent. of the market price. Again the method of taxing arc lamp carbons by weight, without reference to quality, is severely criticised. The difficulties which will arise due to the clause, which states that the tax is to be 0·4 pfennig per unit if the average selling price exceeds 8 pfennig, are then emphasised. In the case of a central station supplying one or two large power consumers at a very low price, the figure of 0·4 pfennig per unit will have to be paid on the consumption of the large users, although it may exceed 5 per cent. of the total generating costs if the average selling price exceeds 8 pfennigs. In conclusion, Dr. Fasolt describes the Bill as the product of an official mode of thought far removed from all practical and economical consideration. The Bill, if passed, he says, will not only retard the progress of the many applications of electricity in the country, but will considerably diminish the country's power of competing with foreign countries.

With regard to the effect of the proposed tax on the coal-mining industry of the Ruhr district, the following figures given in the *Elektrotechnische Zeitschrift* are of interest:—If the estimated yearly consumption of electrical energy is taken at 700 million units for the mines in the Ruhr district, the tax amounts to some £140,000, to which must be added some £10,000 as the amount of the tax on lamps and carbons. By dividing the total of £150,000 by the amount of coal mined per year, which in the case under consideration is some 80 million tons, the extra cost due to the tax amounts to about 0·45d. per ton. As, however, only a few of the mines use electric power to a large degree, the amount may rise to over twopence per ton in these cases.

CORRESPONDENCE

SMALL REMOTE CONTROL SWITCHES.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—In answer to the letter from Wm. P. M. in to-day's issue of your paper, we should be glad if you would kindly put us into communication with this gentleman, as we should be pleased to make him a switch such as he mentions. We should like to know whether the switch is to be both closed and opened automatically, and how he proposes to operate it. Thanking you in anticipation,

Yours faithfully,
For VENNER & Co.,
ERNEST E. SHARP.
(Manager.)

6, Old Queen Street,
Westminster,
London, S.W.
November 26th, 1908.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—Your correspondent will find that he can get the article he requires from Messrs. A. Emanuel & Sons, Ltd., George Street, Manchester Square, London, W., at 4s. 6d. each, plus postage.

Yours faithfully,
W. H. ALLEN,
Borough Electrical Engineer.

Corporation Electricity Department, Bridge Street,
Loughborough, Nov. 27th, 1908.

25-VOLT TRANSFORMERS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—Referring to Mr. A. H. Dykes's letter in your issue of 26th inst., I would advise that the 17-watt total losses for the balancer are the maximum losses when the loads in the various circuits are out of balance—compared with Mr. A. H. Dykes's figures for the same conditions, 28-30 watts. I regret that my previous letter was not quite clear in this particular.

Yours very truly,
K. FAYE-HANSEN.

British Westinghouse Works, Trafford Park,
Manchester, Nov. 27th, 1908.

UNUSUAL FREQUENCIES.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—I recently had occasion to test some single-phase apparatus which was designed for connection to a supply at 80 periods. The highest periodicity which could be obtained from the works supply was 50, and some means had to be taken to increase this to the desired value.

To the three-phase supply the stator windings of a three-phase slip-ring motor were connected. The rotor pulley was belted to that of a variable speed direct current motor, and driven backwards, *i.e.*, in the opposite direction to which it would have rotated under normal conditions, the slip being approximately 200 per cent.

By adjusting the speed at which the rotor was driven it was possible to obtain from the rotor slip-rings exactly the periodicity required.

I think the above method may be of use to some of your readers as it affords a convenient means of obtaining unusual frequencies.

Yours faithfully,
F. J. MOFFETT.

Union Chambers,
Temple Row, Birmingham.
Nov. 28th, 1908.

Institution of Electrical Engineers.—The following is the result of the ballot for new members at the meeting on Thursday:—Member: W. Slingo; Associate Members: F. J. Alsop, J. O. Balshaw, W. B. Boyd, W. Bridges, A. S. Campbell, S. de Beer, A. H. S. MacCallum, J. M. S. Maxwell, L. F. Mountfort, H. V. Pegg, J. Roothaan, F. C. Sellens; Students: E. Barlow, W. J. I. Casewell, A. E. E. Cheal, C. STORAGE BATTERIES ON ALTERNATING-CURRENT SYSTEMS

A PAPER on the above subject was read by Mr. J. L. Woodbridge before the American Institute of Electrical Engineers, at their annual summer meeting this year. In the introduction to the Paper, the author points out that in many cases where alternating currents are developed, the advantages of a regulating storage battery are even more pronounced than in direct-current service. For instance, alternating-current generation is particularly applicable to main railway lines on which heavy trains run at comparatively infrequent intervals, producing fluctuations of load abnormally high as compared with the average. The auxiliary apparatus required in connection with a storage battery adapted for regulating an alternating-current system may, he says, also be used for changing the frequency or controlling the power factor.

The conditions to be met in the various alternating-current systems include a number of different combinations which may be classified broadly in five cases.

The system illustrated in Fig. 1 is that in which alternating current is generated and transmitted to direct-current sub-stations for supplying a direct-current fluctuating load such as that of the ordinary interurban direct-current trolley system. The early applications of storage batteries to systems of this kind involved the installation of a battery at each of the several sub-stations to regulate the fluctuations of direct-current load at that point. This required nothing more than the ordinary direct-current controlling apparatus. The author states that in

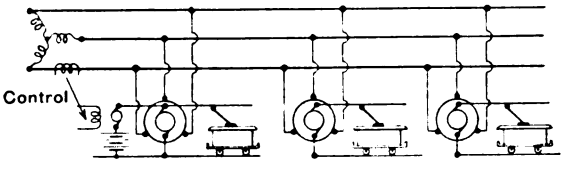

FIG. 1.—ALTERNATING-CURRENT TRANSMISSION AND DIRECT-CURRENT LOAD; REGULATION WITH BATTERY BOOSTER.

some recent installations, however, the conditions have been such that it has been found advantageous to concentrate the battery capacity at one point, a single battery being installed arranged to control the total combined fluctuations of load on the entire system. In cases where the transmission is wholly in one direction from the power house, the nearest sub-station may be selected. In such cases the battery, with its regulating booster, is connected to the direct-current sub-station bus-bars in the usual manner, but the booster is controlled by means responsive to the total alternating-current output of the generating plant. Its control is accomplished by means of current transformers located in the main alternating-current bus-bars or transmission lines, between the converter station and the generators, whose secondaries will furnish alternating-current to the battery controlling apparatus proportional to the total output of the power station. In some cases current transformers are located in the individual generator circuits, their secondaries being connected in parallel to give a combined output proportional to the total generator load.

By this arrangement the same converters which are required for supplying the local direct-current load on the sub-station are also used for transforming the battery current, and in many cases no greater converter capacity is called for on account of this latter function. For example, the total load on the system may vary from 500 to 3,000 kw. with an average of 1,500 kw. The direct-current demand on the sub-station where the battery is located may vary from zero to 1,500 kw. Converting apparatus must therefore be installed at this sub-station of sufficient capacity to handle a momentary load of 1,500 kw. It is evident that with the battery regulating on the total load this converting apparatus will never have to deliver more than 1,500 kw. to the sub-station, since this is the total output from the generators, and this amount of energy will be supplied to this sub-station only at rare intervals when the total load on the rest of the system is zero. Nor will this converting apparatus be called upon to transmit energy in the reverse direction to a greater amount than 1,500 kw., since the total maximum load on the entire system is 3,000 kw., of which the main generator is always supplying 1,500. The general operation of the battery in this scheme is to relieve the sub-station of more or less of its direct-current load at times of increased load on the rest of the system, thus preserving a constant load on the generating units. It being necessary on account of the direct-current load to maintain constant voltage on the direct-current bus-bars, a battery booster will be required to cause the battery to charge and discharge, this booster being controlled from the alternating-current circuit.

The case next considered by the author is illustrated in Fig. 2. Current is generated and utilised as polyphase alternating current, there being no direct-current circuit, under which conditions, of course, the battery (placed either at the main generating station or at the centre of load) will have its

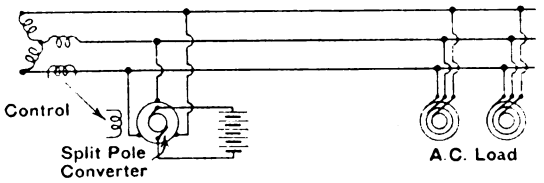

FIG. 2.—ALTERNATING-CURRENT LOAD; REGULATION WITH SPLIT-POLE CONVERTER.

entire output converted into alternating current, so that converting apparatus must be provided of sufficient capacity to handle the maximum battery discharge. If a motor-generator set is used for control, the charge and discharge of the battery may be accomplished by varying the voltage of the direct-current machine in response to fluctuations of the alternating-current load. Synchronous converters are preferred by the author for this purpose, particularly if the fluctuations of load are extremely rapid. If a motor-generator is called upon to transfer energy from the battery to the alternating-current circuit, it will deliver energy to the latter circuit only after its armature has been driven somewhat ahead of its normal phase position, and owing to the inertia of the armature some appreciable time must elapse after the battery has begun to discharge into the direct-current machine before the alternating-current machine is delivering the equivalent energy to the alternating-current circuit, and a time lag is thus introduced. With a synchronous converter this effect is practically eliminated. With the latter type of machine, however, special means must be provided for varying the direct-current voltage at the battery terminals to compel the battery to charge and discharge. If a standard converter is employed, a battery booster may be employed for this purpose, provided with a field-control system responsive to the fluctuations of alternating-current load.

In order to dispense with the battery booster, however, a synchronous converter providing for a variable ratio between the alternating- and direct-current voltages has been developed. This machine has been designated the "split-pole" converter owing to the fact that the control of the transformation ratio is brought about by dividing each pole into two or more sections whose excitations are separately controlled. By this means the direct-current voltage of the converter is varied to cause the battery to charge and discharge while the alternating-current voltage is maintained practically constant. This type of machine, it is claimed, offers considerable advantages in the way of simplification and increased efficiency of operation over apparatus involving boosters or motor-generator sets, and is adapted for handling extremely rapid fluctuations of alternating-current load, in such cases in which a constant-potential direct-current bus-bar is not required.

In the case shown in Fig. 3, power is generated as alternating

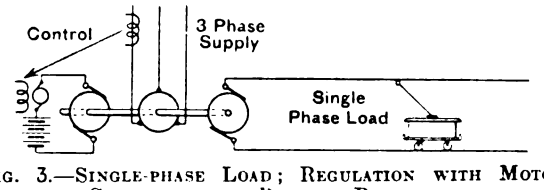

FIG. 3.—SINGLE-PHASE LOAD; REGULATION WITH MOTOR GENERATOR AND BATTERY BOOSTER.

current and is supplied to a single-phase circuit. One of the most noted examples of this class of installation is found at the frequency-changing station of the Spokane & Inland Railway Co. at Spokane, Washington. The equipment of this station includes four frequency- and phase-changing motor-generator sets, each set consisting of three direct connected machines, viz., a 60-cycle, three-phase induction motor of 1,000 h.p. capacity, receiving power from the incoming transmission line; a 1,000-kw., single-phase, 25-cycle, 2,200-volt generator, delivering current to the railroad; and a 750-h.p., 500-volt, direct-

Digitized by Google

current machine, which is connected to the battery and acts as a generator or a motor when the battery is respectively charging or discharging. The battery consists of 275 cells having a capacity of 1,920 amperes at the one-hour rate, and is provided with two motor-driven boosters which may be operated in parallel. The boosters are controlled by apparatus which responds to the current in the incoming 60-cycle transmission line in such a way that small variations of this current vary the booster voltage, thus causing the battery to charge from or discharge into the direct-current machine to absorb the fluctuations of load on the single-phase circuit. This is one of the cases, the author says, in which the financial results from a battery installation may be very clearly demonstrated, inasmuch as the power for the operation of the railway system is purchased on the maximum demand basis, and it is estimated that the reduction in the power bills effected by the battery in relieving the transmission line of load fluctuations will be sufficient to repay the initial investment in about three years.

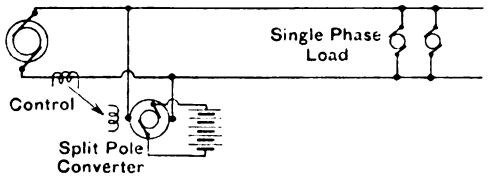

FIG. 4.—SINGLE-PHASE LOAD; REGULATION WITH SPLIT-POLE CONVERTER.

Instead of the scheme above described, he suggests, however, the employment of the split-pole converter running as a single-phase machine connected to the single-phase circuit with suitable transformers. The output of the battery will then be delivered to the railway circuit without the intervention of mechanical transmission, and the efficiency on discharge, and therefore the net alternating-current output for a given battery discharge will be greater. This is illustrated in Fig. 4.

The cases next considered are those in which both alternating-current and direct-current generators supply a load which is partly alternating- and partly direct-current, the two circuits being interconnected by suitable converting apparatus. If the fluctuations of the direct-current load preponderate, a battery booster is required to keep the voltage of the D.C. busbars constant, and this machine must be of sufficient capacity for practically the total battery output. The booster control would not differ in any way from the standard direct-current controlling apparatus. In order to take up the fluctuations on the alternating-current circuit by the battery, the author again suggests the split-pole converter, and as the direct-current busbar voltage is practically constant, only a very small change in ratio of conversion would be necessary, just sufficient to overcome the internal drop in the converter and static transformers.

Another method suggested for providing for this automatic control of the converting apparatus consists in mounting on the shaft of the converter an alternating-current booster whose windings are connected in series between the alternating-current terminals of the converter armature and the collector rings. The field of this booster is controlled automatically in response to fluctuations of load on the alternating-current circuit, thus adding to or subtracting from the alternating-current voltage of the converter and thereby causing it to transmit energy in either

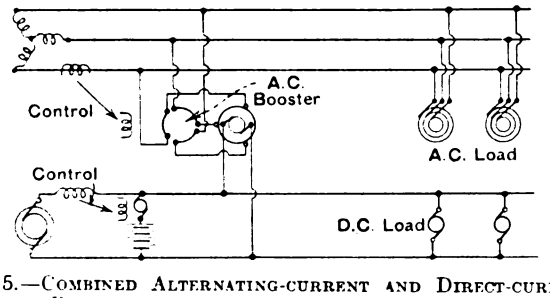

FIG. 5.—COMBINED ALTERNATING-CURRENT AND DIRECT-CURRENT LOAD; REGULATION WITH ALTERNATING-CURRENT BOOSTER.

direction between the alternating- and direct-current circuits as may be required to maintain constant load on the alternating-current generators. This latter arrangement is illustrated in Fig. 5.

When the alternating-current load fluctuations preponderate, a smaller battery booster is, of course, sufficient to handle the fluctuations of direct-current load, if the fluctuations of alternating-current load are transmitted directly to the battery terminals instead of to the direct-current bus-bars. The split-pole converter is again recommended for this purpose, and is in this case connected between the alternating-current circuit and the battery terminal, and so controlled as to transmit directly to the battery the fluctuations of load originating on the alternating-current circuit. This is the scheme which has been adopted for controlling the load fluctuations at the electric power plant of the Indiana Steel Co., at Gary, Indiana. For this plant there is being installed a battery consisting of two series of cells arranged to operate in parallel, each series consisting of 125 cells, having a one-hour capacity of 4,320 amperes. Provision has been made for the future extension of this plant by the addition of two more series of cells of the same capacity. Two direct-current boosters are provided, having sufficient capacity to handle the fluctuations of direct-current load, which will be

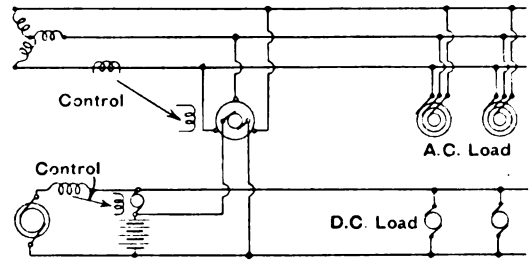

FIG. 6.—COMBINED ALTERNATING-CURRENT AND DIRECT-CURRENT LOAD; REGULATION WITH SPLIT-POLE CONVERTER AND BATTERY BOOSTER.

only a small part of the total load fluctuations. For handling the fluctuations of alternating-current load a split-pole converter of 2,000 kw. capacity is being installed, designed to provide a range of direct-current voltage from a minimum of 200 to a maximum of 300 volts with constant alternating-current voltage. The regulating field of this converter will be controlled by a special alternating-direct-current exciter, designed as described hereinbelow. Provision has been made for a second converter of the same design and capacity. This case is illustrated in Fig. 6.

AUXILIARY APPARATUS.

Under this heading the author describes as follows three pieces of auxiliary apparatus which have been developed for controlling the operation of a battery in connection with an alternating-current circuit:—

The first of these devices, the carbon regulator, calls for only passing notice, as its general design and operation are well known in connection with direct-current regulating plants. It is shown diagrammatically in Fig. 7, in which x and y are two piles of carbon discs subjected to variable pressure by means of the lever, L, which is pivoted between the two piles in such a way that any motion of this lever will increase the pressure on one pile and decrease that on the other. At one end of the lever is an adjustable spring, T, while from the other end is suspended the iron core of a solenoid, S, which carries the current to be regulated, or a current proportional thereto. The two carbon piles are electrically connected in series across the battery, B, while the field coil, F, which is to be controlled, is connected between a point in the circuit between the two carbon piles and the middle point of the battery. The variation of resistance in the two piles due to change of pressure causes a flow of current in one direction or the other through the field coil, F, which is therefore made responsive to the current in

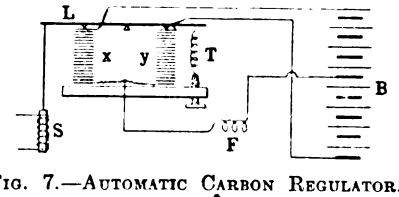

FIG. 7.—AUTOMATIC CARBON REGULATOR.

the solenoid, S. The application of the regulator to alternating-current control involves the substitution of an alternating-current solenoid for the usual direct-current coil. In those installations where the power factor is normally maintained approximately at unity, such as the usual alternating-current generating plant supplying current to converter sub-stations for direct-current railway service, a single coil supplied with alternating current proportional to the current output of the alternators will give entirely satisfactory results, this current being practically proportional to the true watt output of the machines. If, however, the power factor is normally consider-

Digitized by Google

ably less than unity, or if it is subject to wide variations, it may be necessary to control the carbon regulator by means responsive to the energy component of the current and two coils may be used, one of which will produce a constant magnetic flux, while the other carries current which is in phase with the flux at unity power-factor, or whose energy component is in phase with the flux at power-factors other than unity.

The second piece of regulating apparatus which has been developed for this class of service is the split-pole converter. This machine is constructed with each pole sub-divided into three parallel sections with suitable windings for varying the relative excitation of the three sections, the object being to secure a variation of direct-current voltage while maintaining

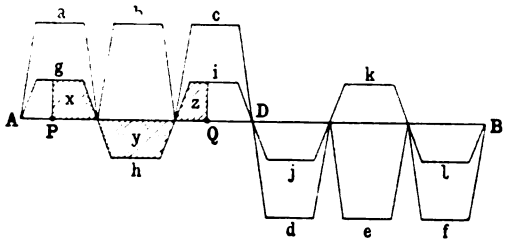

FIG. 8.—DIAGRAM OF FLUX DISTRIBUTION OF SPLIT-POLE CONVERTER.

a constant alternating-current voltage. The theory upon which this design was based may be illustrated by reference to Fig. 8, in which is shown an assumed distribution of field flux around the periphery of the armature. The line, A B, represents the developed armature periphery, the direct-current brushes being located at A and D. The lines a, b, and c, represent the field strength of the three sections of one pole, and the lines d, e, and f, that of the other pole under normal conditions of excitation. The result of this excitation will be a certain ratio between alternating- and direct-current voltage. If, now, the excitation of the outer pole sections a, c, d, and f, be increased, and that of the middle sections b, and e, be decreased, the field distribution may then be represented as the resultant of the auxiliary field, g, h, i, j, k, and l, superposed upon the normal field. If, now, we consider the electromotive force developed in a section of the armature between the points P, and Q, which may be taken to represent two of the three phase taps located 120° apart, it will be seen that the auxiliary field will have absolutely no effect on the voltage in this section at any point in the revolution; for the sum of the shaded areas x, and z, is always equal and opposite to the shaded area y. The auxiliary field therefore interposes into the armature section between the points P, and Q, equal and opposite amounts of field flux, which exactly neutralise each other in the generation of electromotive force between P, and Q. The effect, however, of the auxiliary field on the direct-current voltage between the points of brush contact A, and D, is to produce an increase in that voltage for the reason that between these two points there are two areas of positive flux and only one area of negative flux due to the auxiliary field. Theoretically, therefore, this auxiliary field would produce an increase or decrease in the direct-current voltage without any effect whatever on the magnitude or wave shape of the alternating voltage, between the points P, and Q, provided these points are spaced 120° apart. Practically, however, it is necessary to allow a neutral area of zero field strength at the points A, and D, for commutation. This modification produces some disturbance of the wave shape of the alternating counter electromotive force, which, however, is not sufficient to interfere with the practical operation of the machine.

The third piece of auxiliary apparatus described is an exciter designed to control the regulating field of a booster or split-pole converter in response to variations of load on an alternating-current circuit. This machine is illustrated in Fig. 9, and as there shown consists of an armature, B, provided with a bi-polar winding revolving in a four-pole field frame. This armature is connected by suitable collector rings (not shown in the drawing) to the secondary windings of three current transformers T_1, T_2, T_3, whose primaries are connected in series with the alternating-current circuit 1, 2, 3, supplied by a source, A, whose load is to be controlled. The alternating current thus transmitted through the armature winding would, if the latter were stationary, produce a revolving field proportional to the output from the source, A. The armature is, however, rotated by means of a synchronous motor in the opposite direction to that of the field rotation so as to hold this field stationary in space. There will result a stationary field whose axis is in the line of the arrow, K_1. A commutator, C, is connected to the armature winding upon which bear two pairs of brushes, 4–5 and 6–7. The effect of the field K, would be to produce a direct-current electromotive force between the brushes 4 and 5. A shunt winding, 8, on the four poles of this machine, controlled by the rheostat, R, may be adjusted to neutralise the field K_1 at any predetermined output from the source, A, thus reducing the electromotive force between the brushes 4 and 5 to zero. These latter brushes are then short circuited. If now, a slight increase of load on the source A should occur, the field K_1 would no longer be neutralised by the shunt field winding and an electromotive force would be produced between the brushes 4–5, causing a considerable flow between these brushes. This flow produces a secondary field, K_2, at right angles to the first, and of appreciable magnitude; and this second field produces an electromotive force across the other pair of brushes, 6–7, which are connected to the regulating field, F. In series between the brush, 7, and the corresponding terminal of the field, F, is connected a series winding on the poles of the exciter, designed to neutralise the magnetomotive force of the current through the armature winding between the brushes 6 and 7, so that the output from these brushes will have no disturbing effect on the exciter field.

This type of exciter possesses a number of important features in connection with alternating-current regulation, which may be briefly enumerated as follows:—(1) It will be seen that it acts as a multiplying device by reason of the magnifying effect of the current between the short-circuited brushes, and can therefore be made exceedingly sensitive to small changes in the alternating-current load. (2) It can be made to respond to any desired phase component of the alternating current by a suitable angular relation between the exciter armature and the armature of the synchronous motor which drives it. Thus for controlling the charge and discharge of a storage battery this exciter would be adjusted to respond to the energy component of the alternating current. (3) For controlling the power factor on the alternating-current circuit the two pairs of brushes, 4–5 and 6–7, may be interchanged so that the latter are short-circuited while the former are connected to a field winding on any synchronous apparatus connected to the alternating-current circuit. The

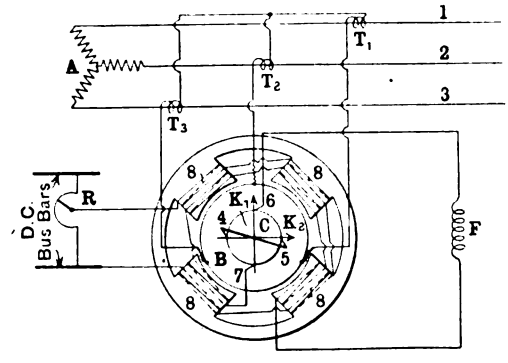

FIG. 9.—AUTOMATIC FIELD CONTROLLING EXCITER FOR BOOSTER OR SPLIT-POLE CONVERTER.

exciter will then be responsive to the wattless component of the alternating current, and can be made to control the field of the synchronous apparatus in such a way that this apparatus will supply practically all or any desired proportion of this wattless current. For controlling both the energy fluctuations and the power-factor two such exciters may be operated, one of which is responsive to the energy component and the other to the wattless component of current.

Another advantageous feature of this exciter lies in the fact that the secondaries of the current transformers may be short-circuited at any time, with the result of merely killing the regulating function. It is not necessary to disconnect the connections to the collector rings before doing this, even with considerable excitation in the shunt-field winding of the exciter, since the armature reaction is so great that a short-circuit will produce only a nominal flow of current sufficient to demagnetise the fields. Similarly, in putting the apparatus into service the rheostat, R, if properly calibrated, may be set for any desired constant load on the source, A, and, after all, the main connections are closed so that the battery is merely floating on the system, the short-circuiting switch across the secondaries of the current transformers may be opened and the load on the source, A, will immediately be held at the constant predetermined value for which the rheostat, R, has been set.

A COMPARISON OF NATURAL AND INDUCED DRAUGHT SYSTEMS

WE give below a report of the discussion which followed the reading of Mr. W. N. Y. King's Paper with the above title at the meeting of the Leeds Local Section of the Institution of Electrical Engineers on November 25th. The Paper itself, which was given at some length in our last issue (page 701), contained figures giving the cost of a particular plant and sketches showing its arrangement, a set of curves connecting height of chimney, draught pressure, and chimney temperature in the case of natural draught, and also a number of general considerations with regard to induced draught plant.

Mr. J. R. Williams (Sheffield Tramways), in opening the discussion, said there was nothing to be gained by raising the temperature of the gases in the chimney to above 400° F. The ideal method for a steam plant was to have all the boilers connected to one main flue, using natural draught for ordinary loads, and induced draught for peak loads. This would entail a minimum capital outlay with high efficiency.

Mr. Graham (Sheffield) did not feel able to criticise the Paper at length, as he had not previously had an opportunity of reading it, but he would have liked the author to have given more comparisons of results obtained with both systems. Speaking from an extensive experience with induced draught, he detailed several installations where a considerable increase in efficiency had been obtained by its adoption. Not only a large saving in fuel, but less boiler power was required to obtain the same amount of steam. Referring to the question of pre-heating the air by means of the heat in the flue gases, he affirmed that for every degree of heat extracted from the gases, the furnace temperature was increased two degrees. In comparing the relative costs of the two systems, the correct method would be to include the whole cost of the boiler plant. In an installation of over four boilers, the first cost of an induced draught system with hot-air economiser was less than with natural draught. The speaker referred to a patented system of combined forced and induced draught which allowed the furnace doors to be opened for stoking without letting in cold air, thus overcoming a prejudice which at present exists against the use of these systems.

Mr. W. B. Woodhouse (Yorkshire Electric Power Co.), in criticising the tests given in the Paper, said they were difficult to analyse, owing to the many assumptions included. It was a frequent though unfortunate practice in Papers dealing with efficiencies of steam plant to consider the combination as a whole, whereas the efficiency of the boiler should be treated separately from that of the combustion. He would like to know how much the efficiency was improved or altered by increasing the draught by fractions of an inch.

Mr. R. H. Campion (Electricity Works, Dewsbury) considered it would be preferable to design a natural draught plant in the first place on modern lines, using expanding flues, &c. Induced draught was usually only added to overcome original bad design. Referring to the heat losses, those resulting from banking the fires were always very great, and should be guarded against. In his opinion, one of the chief drawbacks to the induced draught system was the difficulty experienced in keeping the bearings of the motors cool.

Mr. Wilson Hartnell (Leeds) pointed out that to obtain the best results with induced draught, the plant must be totally redesigned as the conditions were so different. A quick combustion was far more economical for high evaporations. Although there were advantages with induced draught, the mechanism required renewing more often than a chimney. For natural draught the chimney should be designed so that it would carry away all the gases with a draught of about 10 ft. per second.

Mr. H. Dickinson (City Electrical Engineer, Leeds) was of the opinion that for a constant and steady load there was no advantage in induced draught. For central station work it, however, was a considerable help for peak loads. At night it enabled one to keep less standby boilers in service, and reduced the number of boilers necessary for the load. He noticed there was no mention about trouble from grits coming out of the chimney. In Leeds they had trouble in this respect, although the chimney was 210 ft. high, and many plans had been tried to overcome the difficulty.

Mr. King, in reply, agreed there was no advantage to be gained by increasing the temperature in the chimney above 400° F. The life of a brick chimney might be taken at 100 years, and a fan outfit at about 10 years. The base of a steel chimney, if self-supporting, must be well splayed out, nearly as large as a brick chimney. He agreed the capital cost of economisers should be included, but he had found it difficult to include everything in a short Paper, which was written more with the intention of promoting a discussion than as a complete Paper on the subject. The bearings of the motors should be amply designed, and in practice did not give trouble if properly water cooled. The smoke problem, he said, was really a question of proper combustion. Replying to Mr. Dickinson's remarks re trouble with grits coming out of the chimney, he admitted that such was the case, but in Sheffield it was only small compared with what was ejected from neighbouring steel works.

FIRES ON TUBE RAILWAYS

THE Fire Brigade Committee of the London County Council have reported upon the question of precautions against fires in underground railways. This is mainly due to a report by the chief officer of the fire brigade on the fire which occurred on July 16th, 1908, on the City and South London Railway. In this report the following recommendations are made :—

(1) The fire appliances on all tube railways, whether constructed before or since 1904, should be periodically inspected by the chief officer of the fire brigade with a view to seeing that they are efficiently maintained, and in making such inspection the chief officer should deal with any points which may occur to him affecting the general question of protection from fire, and should communicate direct to the Board of Trade any suggestions which he may desire to make.

(2) There should be provided on all tube railways, whether constructed before or since 1904, automatic signal lights, or preferably an illuminated sign, which would show on the platforms of the stations concerned and also on the street level when the current to the live rail is cut off in either direction.

(3) The owners of all tube railways constructed before 1904 should be called upon to comply, with as little delay as possible, with the requirements made in that year, or if this is considered impracticable, such railways should at least be provided with—(*a*) fire-appliances as far as possible in conformity with the minimum requirements made in 1904; (*b*) a hydrant, with sufficient hose, fitted 100 yards down each tunnel from each end of each platform; and (*c*) an incombustible platform between and at the sides of the rails for persons to walk upon.

(4) The minimum requirements, &c., as regards fire-appliances made in November, 1904, should be varied by the omission of the observation (*d*) as to the fire brigade being practically of no avail in the event of a fire obtaining a hold in a tube railway and the substitution therefor of the following observation—"In the event of a fire in a tube railway not being readily extinguished by the railway employees, notification should be immediately given to the fire brigade by telephone and by the nearest fire-alarm."

The Supply of Tungsten.—In view of the fact that a large amount of tungsten is now being used in the manufacture of metal filament lamps, the following information with regard to the sources of the minerals from which the metal is obtained is of interest. The chief ores are wolframite and scheelite, the former a tungstate of iron and manganese containing up to 76 per cent. tungstic acid, the latter tungstate of lime containing up to 80 per cent. tungstic acid. As was mentioned in a short article on the subject on page 23 of Vol. III. of Electrical Engineering, the greatest producing locality in the United States is Boulder County, Colorado, where the ore occurs as a wolframite breccia. A small amount of wolfram is found in the tin mines of Cornwall, but it has only been separated recently. The mines in Portugal have a good output, and the amount exported increased from 9 tons in 1905 to 570 tons in 1906. Valuable deposits of wolfram exist in the Nagpur district of the Central Provinces of India, and the deposits in Queensland are still being worked with great success.

Physical Society Exhibition.—The annual exhibition of apparatus is to be held by the Physical Society on Friday evening, December 11th (from 7 p.m. to 10 p.m.), at the Royal College of Science, South Kensington. The following firms will be among those exhibiting :—Cambridge Scientific Instrument Co., Casella & Co., A. C. Cossor, Ltd., J. H. Dallmeyer, Ltd., Elliott Bros., Everett, Edgcumbe & Co., Gallenkamp & Co., Gambrell Bros, J. J. Griffin & Son, A. Hilger, Ltd., India Rubber, Gutta Percha & Telegraph Works Co., Marconi's Wireless Telegraph Co., Nalder Bros. & Thompson, Newton & Co., R. W. Paul, James Pitkin & Co., Siemens Bros. & Co., Snell & Tinsley, J. Swift & Son, Alexander Wright & Co., and Carl Zeiss, Ltd. From the programme, of which we have received an advance proof, there appear to be many items of considerable interest to both physicists and electrical engineers. We understand that invitations have been given to the Institution of Electrical Engineers, the Faraday Society, the Optical Society, and the Röntgen Society. Admission, however, except to Fellows of the Physical Society, will be by ticket only, and therefore members of the societies just mentioned desiring to attend the exhibition should apply to the secretary of the society to which they belong.

INCANDESCENT LAMPS

A PAPER was read recently by Mr. J. Findlay before the Rugby Engineering Society on incandescent lamps. The first part of the Paper was devoted mainly to the carbon filament lamp, and was prefaced by some introductory historical remarks.

"Reading over early patent specifications," he says, "it is difficult to understand why some of the lamps there described were not successful. It is probably the case that some of the inventors lacked perseverance, and discontinued their efforts on encountering difficulties. One is confirmed in this view on coming to Edison's specifications. It is quite plain that he kept trying one thing after another with great perseverance, and when he struck the right track he went into the work with great thoroughness. The first British patent to be classed under "Incandescent Lamps" was granted to A. N. Lodiguine, of St. Petersburg, in 1872. The first to mention an exhausted glass vessel was granted to S. W. Konn, in 1875 (Konn was, I think, the agent of Lodiguine). A patent granted to C. W. Harrison, in 1878, describes the manufacture of metallised carbons. Edison's first patent is dated October 23rd, 1878, and very curiously, in addition to mentioning carbon as a possible material for the filament, it mentions, among other things, titanium oxide and osmium, or other metals having a high melting point. In the following month, Edison filed another application, in which mention is made of zirconium oxide, silicon, and boron, all materials which have figured largely of late in the efforts to find substances of higher efficiency than carbon. Edison's patent, dated November 10th, 1879, speaks of 'a carbon filament of high resistance in a vacuous glass bulb.' This sentence aptly describes the carbon filament lamp of the present day."

The Paper then dealt with the defects which have to be watched for in incandescent lamps, emphasising more particularly the results of a bad vacuum. If the bulb is insufficiently exhausted, and enough residual gas is left in it to conduct across from one platinum wire to the other, the normal current of the lamp will be a very small part of the total current which may pass over the leading-in wires. It is even stated that as much as 25 amperes will pass as a vacuous discharge in a poorly-exhausted lamp. Manufacturers generally test the vacuum of their lamps on a spark coil, and judge the vacuum by the glow. A method which is much handier for the purchaser is to tap the bulb sharply with the finger, and notice the vibration of the filament. If the filament continues to vibrate for some time and comes to rest gradually, the vacuum is good, but in the case of a poor vacuum the filament will very soon cease to vibrate.

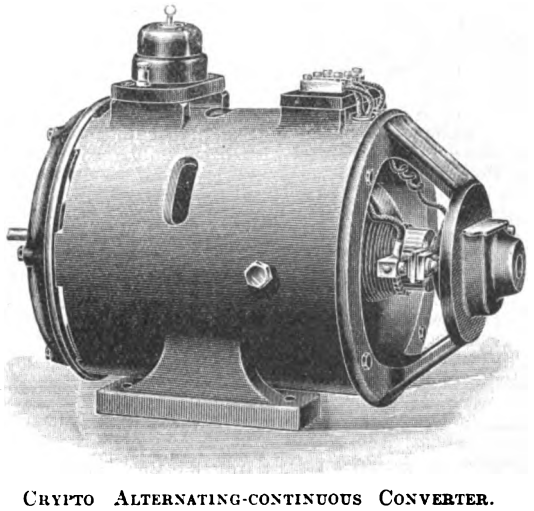
The subjects of candle-power efficiency, life testing, and effect of variation of voltage on carbon filament lamps were then briefly dealt with, and in the latter portion of the Paper the author passed on to speak of metal filament lamps, continuing as follows:—

"The idea of using tungsten for filaments is not new, but the successful manufacture of filaments made from this metal is, on a commercial scale at least, quite recent. In January, 1893, A. de Lodiguin, a Russian, residing in Pittsburg, Pa., filed an application for a United States patent for a method of manufacturing filaments from tungsten, molybdenum, and chromium. Lodiguin seems to have devoted most of his attention to chromium, which later investigation proves has not the possibilities of tungsten. Certain patentees apparently claim for themselves the sole right to manufacture filaments of *pure* tungsten, although the patent specification in which this claim is made describes a method of manufacture which results in a trace of carbon being left in the filament, while Lodiguin's specification, now almost 16 years old, describes a method of manufacture which leaves positively no trace of carbon or other impurity.

"The tungsten lamp has not yet been in use for a long enough period to enable us to tell how it will act under different conditions with the same precision that we can now do regarding carbon filament lamps. The efficiency of the tungsten lamp is sometimes advertised as 1 watt per candle. This is undoubtedly done to increase its superiority in efficiency in comparison with other types of lamps, but it appears to be overstating the case. Advertisers take advantage of the fact that this lamp, being of Continental origin, has in its home been rated in watts per hefner, and they, when advertising the lamp here, apparently see nothing wrong in translating hefner into candle, while failing to change the figures to correspond with the changed unit. A hefner unit is about 10 per cent. less in value than a British parliamentary candle, so that the equivalent of 1 watt per hefner is 1·1 watts per candle. This is too high an efficiency at which to rate lamps for use on the ordinary supply lines. It might be all right under ideal conditions, say where the voltage was never more than one per cent. above normal. It is very often stated that on account of the resistance of a tungsten filament increasing with temperature instead of decreasing, as in the case of carbon filaments, that the tungsten lamp is far less susceptible to change of voltage than the carbon filament lamp, and that the life is not so adversely affected by a rise in voltage. This may all be true when the efficiency is 1·1 watts per candle-power or poorer, but when we operate the lamp at efficiency of over 1·1 watts per candle, there is reason to doubt if all of this statement will still hold. Figures are not readily available, but there is reason to believe that the life of a tungsten lamp burning at 1¼ watts per candle, is four times as long as it would be if burned at 1 watt per candle-power. This difference in temperature will be caused by a difference of 10 per cent. in voltage, and will be accompanied by a rise of 40 per cent. in candle-power, and 5½ per cent. in amperes. Making calculations to get the total cost of light, we find that if we pay 4½d. per unit for current and 4s. for lamps, a 30-candle-power lamp, burning for 250 hours at 1 watt per candle, will cost 32·7 pence per 100 hours, while a 30-candle-power lamp, burned at 1¼ watts per candle for 1,000 hours, will cost 21·7 pence per 100 hours. So long as lamps remain at their present price, there can be no economy in burning them at anything under 1¼ watts per candle, and it will probably pay to buy lamps even when rated at 1¼ watts per candle, of a voltage two or three per cent. higher than the declared voltage, so that the lamps may be able to withstand temporary rises in the line voltage. Experience reported from the United States confirms this view. When the tungsten lamp was first put into service in America, many complaints were made of bulbs blackening and of early burn-outs. Reports were made later from many different points that this trouble had been overcome to a large extent by ordering lamps of a voltage five per cent. higher than the voltage of the supply line."

A SMALL ALTERNATING-CONTINUOUS CONVERTER

THE accompanying illustration represents a compact and convenient set, forming a combined alternating-current motor and continuous-current generator, specially intended for charging ignition cells from alternating-current mains. The makers of the apparatus, the Crypto Electrical Co., of 155 and 157 Bermondsey Street, S.E., have for some time specialised in this class of apparatus, but the machine illustrated is an entirely new pattern, re-designed throughout. With the old, well-known set it was not possible to take more than about 100 watts output from the secondary side without overheating, and as a somewhat larger output is generally convenient, both the motor and generator have been enlarged. The present set is listed for seven amperes at 15 volts, but can easily be loaded up to eight



Crypto Alternating-continuous Converter.

amperes or 120 watts. Carbon brushes are now used instead of copper gauze. The motor is a single-phase induction motor, and is provided with an auxiliary starting winding. In order to prevent this winding from being left on after the motor has been brought up to speed, a double-acting tumbler switch is provided. To start the motor, the knob is pressed one way, and after it has gained its normal speed, the knob is pressed back the other way. In the first position the starting and running windings are in parallel, and in that position the switch will open unless held over. In the second position, the running winding only is in circuit. If the switch is put in the second position first, the motor will not start, but no harm is done.

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY

IN the *Elektrochemische Zeitschrift* of November, Dr. O. Froelich contributes an interesting article upon a new copper winning process. He first describes the present processes, where it is necessary to roast, then furnace, and finally refine the copper electrolytically or by further furnace methods. The great advantage of electrolytic over furnace refining, although it is more expensive when worked for copper alone, is the easy recovery of the noble metals, gold, silver, and platinum. A satisfactory process for producing copper from its ores directly by leaching out and then electrolysing has not up to the present been found. The method here described depends not upon roasting copper sulphide ores, as has heretofore been done, and driving off the sulphur as sulphur-dioxide, but in heating it out of contact with air to a temperature of from 200°–800° C. The copper ore is then converted into cuprous sulphide, and iron sulphide with liberation of sulphur.

$$2\ FeCuS_2 = Cu_2S + 2FeS + S.$$

The sulphur can thus be directly obtained, and there is no necessity to have a sulphuric acid plant built in the neighbourhood of the works, which must be done if sulphur as sulphur dioxide is to be saved.

The ore, after heating, is leached out with ferric chloride, which dissolves the copper, converting it into cupric and cuprous sulphide. A particular form of digester is employed for this, which consists of a wooden vat, having suspended in its centre a porcelain or wooden perforated cylinder. Within this cylinder there is a wooden screw which lifts the liquid and throws it over the top of the cylinder into the upper part of the vat, solution from the lower part where the cylinder is surrounded by the broken ore running in to take its place. This method of circulation causes a very thorough circulation of the liquid.

Iron is then added to the leaching liquid. The copper is thrown out, and the iron passes into solution. The copper is then washed and cast into ingots. These can either be purified by electrolytic means or by furnace methods. One interesting point is that the noble metals are obtained in the leaching solution, and can be readily recovered from this by electrolytic means. Either poor or rich copper ores may be used satisfactorily for this process. For example, with ores containing only 1 per cent. of copper, not more than 0·1 per cent. is left in the gangue after it has been leached.

According to the German Patent No. 195.033 of Messrs. Siemens & Halske, electrolytic zinc can be obtained in a compact form from solutions of zinc sulphate without the employment of a diaphragm by employing anodes of compact lead peroxide. The anodes may either have a metal core, coated with the peroxide, or may be made entirely of compact lead peroxide.

Electrical Engineers' Ball, 1909.—It has been decided to hold the 1909 ball on Friday, February 5th, at the Hotel Cecil. A large and influential committee has been formed, with an executive committee consisting of the same gentlemen as on the last occasion. The honorary treasurer is Mr. Robert Hammond, and the honorary secretaries are Mr. A. M. Sillar and Mr. H. Alabaster.

Rugby Engineering Society.—The proceedings of this society for the session 1907-8 have just been published. Besides the various Papers read before the society and reports of the discussions, the volume includes a list of the officers for the session, the rules of the society, the library list, a list of the premium awards for the last five sessions, and other information with regard to the society. Among the Papers included is one on the Diesel engine, by A. E. Thompson, and another by A. W. Graeme on the "British Locomotive." The Paper by Mr. Bernard Hopps on petrol-electric systems for motor omnibuses (see ELECTRICAL ENGINEERING, Vol. III., p. 275), which contained a complete description of the British Thomson-Houston Co.'s petrol-electric system, is also in this volume. Lastly, there is a Paper by H. O. Eurich and F. P. Whitaker on the "Systematic Design of Direct-Current Stationary Motors."

Covered-top "Electrobuses."—In a note on page 444 of ELECTRICAL ENGINEERING for September 17th, 1908, it was announced that the London Electrobus Co. would soon put in service in London buses with top covers after the style of those employed on tram-cars. On Saturday last a trial run was made with the first of these 'buses in the Strand and other main thoroughfares, and as soon as the sanction of the police authorities has been obtained, the 'bus will be put into public service. The fact that the accumulators, which weigh nearly 30 cwt., are hung below the level of the wheel axles, causes the centre of gravity to be quite low, in spite of the extra weight of the cover on top. The seats on top are arranged transversely, as is usual, but with a gangway down either side instead of one in the centre. It is stated that the present takings of the company average 14d. per car mile, which means that each 'bus earns some £500 annually. There are 20 'buses now in service.

THE PARLIAMENTARY SESSION OF 1909

IN addition to the proposals, of which particulars were given in our last issue, notices have also been given of the intention to deposit the following Bills in the Parliamentary Session of 1909 :—

The promoters of the North and South Shields Electric Railway, which was authorised in 1902, seek an extension of time granted by their original and subsequent acts for the completion of work and the acquisition of land. Powers to raise new capital are also asked for.

An extension of time will also be sought by the promoters of the South-Western and Isle of Wight Junction Railway for a proposed electrically-operated railway connecting the mainland of Hampshire with the Isle of Wight, which was authorised in 1901. A similar application will be made with regard to the Preston, Chorley, and Horwich tramways, which were authorised in 1903.

New tramways are proposed in a Bill by the Keighley Corporation.

Electric Lighting Provisional Orders will be applied for by the Coast Development Corporation for supply in Walton-on-Naze; Southampton Corporation, for the parishes of North and South Stoneham; Stourbridge Urban District Council; Aldershot Gas and Water Co. (Camberley); Christey Bros., Ltd. (Holsworthy); Biddulph Gas. Co.; Wells Gas Co.

Tramways Provisional Orders will be applied for by the Northampton Corporation and the Bolton Corporation.

LONDON TRAFFIC

THE Prime Minister, on Thursday afternoon, received a deputation from the London County Council respecting the traffic of London. The deputation was introduced by Mr. R. A. Robinson, Chairman of the London County Council, who was followed by the Hon. W. R. Peel, who urged upon the Government the necessity for taking into consideration the question of the traffic in the whole of the area of greater London. At present, although the traffic had increased to 1,280 millions from 259 millions in 1881, there was no co-ordination between the large number of different companies and authorities, who were all competing with each other. The views of the London County Council were that, having a tramway undertaking of their own, they preferred the creation of an Advisory Board upon the lines recommended by the Royal Commission on London Traffic, in 1905. In his reply Mr. Asquith first of all pointed out that he was not a free agent in this matter, the subject being one which closely concerned the Board of Trade and the Local Government Board. At the same time he confessed that the question had not greatly occupied his own attention. He gathered from the deputation that insuperable objections were foreseen to any proposal that the London County Council should deal with the question on the lines laid down by the Royal Commission, and he further gathered that any authority which might be created by the Government should not exercise executive functions and still less coercive functions; in fact, the authority recommended would be a kind of intelligence department on this particular question. Of course it was clear that the authority might make suggestions to the Government, but he thought there were strong objections to setting up another authority in London if it could be possibly avoided. London suffered rather from a superfluity of authorities in this connection, but at the same time he was greatly struck with the want of co-ordination as regards routes and competing forms of traffic. For the present, however, he did not think he could do more than promise to most carefully consider all the points brought forward by the deputation.

The Trackless Trolley System in Germany.—In the reports prepared by the Dundee and Manchester Tramways Committees on the trackless trolley system, abstracts of which were published in ELECTRICAL ENGINEERING for July 30th and October 1st respectively, descriptions were given of the cars and equipment in the German town of Mulhausen. This is the latest example of the system, and the following notes from the *Mulhausen Tagblatt* regarding the working and proposed extension of the line are of interest. On a certain Sunday in October last, 1,434 passengers were carried, and the receipts amounted to over £10, which works out at just over one shilling per car mile. The current consumption amounted to 1·42 kw. hrs. for the 200 car miles run, as measured at the power station. The line losses amounted to 3·9 kw. hrs. This gives a total consumption of 710 watts per car mile. Each car carries twenty passengers, and weighs 54 cwt. unloaded. The total length of line working at present is two miles, and the cars run every twelve minutes on week-days, and every six minutes on Sunday afternoons, when a large number of passengers are carried to the Zoological Gardens. An extension of over six miles of route is to be made soon. On one portion of the proposed route the gradient is as much as 9·2 per cent., or 1 in 12·2.

LONDON ELECTRIC POWER BILLS

BOTH the London Electric Supply and the London (Westminster and Kensington) Electric Supply Bills have now been passed by Sir Luke White's Committee of the House of Commons, and reported for third reading. The following account gives briefly the contents of the Bills as they have now been reconstituted in consequence of the decisions of the Committee, and affords a clearer idea of the cumulative effect of the various decisions than if we were to give them piecemeal in the sometimes contradictory and confusing form in which they were given during the Committee proceedings. Special attention may be drawn to the report of the London County Council upon the London Electric Supply Bill.

London Electric Supply Bill.

This Bill now provides that the authorised undertakers within the County of London, or any two or more of them, with the approval of the Board of Trade, may enter into and carry into effect agreements for mutual assistance both with regard to the giving and taking of a supply, and of the management and working of their generating stations or undertakings generally. Mains may be carried through the districts of intervening authorities, the protection afforded to such authorities being that they may call for a supply of electrical energy upon the same terms as those agreed between the undertakings linked up by the mains running through the intervening district. A maximum price has been inserted in the Bill for power supply at the rate of £6 15s. per kw. per annum of maximum demand, plus 0·5d. per unit where the maximum demand is not less than 2 kw. The companies supplying upon these terms may demand a contract for seven years, the consumer agreeing to pay an annual sum of not less than 20 per cent. upon the capital outlay respecting the supply.

The clause authorising the supply of energy for haulage, traction, &c., stipulates that energy shall not be supplied under this section for use in the London Docks, St. Katherine Dock, or the Regent's Canal Dock, in the Metropolitan Borough of Stepney, to any dock within the Metropolitan Borough of Poplar or to the Victoria Dock, which is in West Ham, without the consents of the respective local authorities.

Clauses are also inserted for the protection of the railway companies, Metropolitan Water Board, &c., and special reference may be made to the clause for the protection of the Royal palaces, parks, &c. This gives the engineer to the Commissioners of Works authority to inspect any generating station, and if in his opinion proper precautions are not being adopted for the consumption of smoke and for reasonably preventing the evolution of oxides of sulphur, and generally for the prevention of nuisance in relation to Royal palaces, parks, &c., the undertakers may be called upon to remedy this defect.

The clause constituting the London County Council the purchasing authority in lieu of the Borough Councils, is given in full below :—

(1) From and after the passing of this Act every power to purchase any Undertaking or any part of any Undertaking of a Supply Company which but for this section would have been exercisable by a local authority in any part of the Administrative County of London under the provisions of Section 2 of "The Electric Lighting Act, 1888," shall be and is hereby transferred to the London County Council (in this Section called "the Council"), and shall, subject to the provisions of this Section, be exercisable by the Council in lieu of and in substitution for the local authority, and the Council shall also be empowered to purchase all the Undertakings (or parts of Undertakings) in the said County of all the London Electric Supply Companies not purchasable by a local authority.

Provided that the Council shall give not less than three years' notice of their intention to exercise such power and that from and after such purchase all powers now vested in the London Electric Supply Companies in regard to the Undertakings (or parts of Undertakings) so purchased shall vest in and be exercisable by the Council in lieu of and in substitution for the said Companies and shall cease to be exercisable by the said Companies.

(2) The Council shall not give notice of their intention to purchase nor shall they purchase the Undertaking or any part of the Undertaking of a Supply Company unless they shall at the same time give notice of their intention to purchase and shall purchase upon the terms hereinafter defined all the Undertakings or parts of Undertakings of all the London Electric Supply Companies which the Council are in pursuance of this Section empowered to purchase.

(3) The Undertakings of the several London Electric Supply Companies shall if purchased by the Council be paid for upon such terms if not agreed upon as an Arbitrator may determine to be equitable having regard to all the circumstances of the case, including the date at which the Undertaking or part of the Undertaking became or would become purchasable, and in fixing such terms the Arbitrator shall in no case award less than the price which would have been payable to the Company under and in accordance with the provisions of Section 2 of "The Electric Lighting Act, 1888," if the local authority had exercised the powers of purchase under that Section, taking into consideration the date at which such purchase might take place or have taken place, and in the case of the City Undertaking of the Charing Cross, West End, and City Electricity Supply Co., Ltd., less than the price which would have been payable to that Company under and in accordance with the provisions of "the City of London Electric Lighting Order, 1899."

(4) The date at which the Council may proceed to purchase the undertakings of the London Electric Supply Companies in pursuance of any such notice as aforesaid shall be the twenty-sixth day of August one thousand nine hundred and thirty-one, and if the Council shall not have served notice as aforesaid for purchase at that date, they may, upon given notice as aforesaid, purchase such Undertakings at the expiration of any subsequent period of ten years.

(5) After the passing of this Act the Undertaking (except Undertakings or parts of Undertakings used wholly for the supply of electricity outside the Administrative County of London) of the London Electric Supply Companies shall cease to be purchasable otherwise than in accordance with the provisions of this Section.

The purchase money may be paid in stock to the extent of one-half, the remainder to be paid in cash.

Clause 24 stipulates that the County Council shall advance to the Company during the three years' notice the necessary sums for developing the undertakings during that period upon a rate of interest which the Treasury may determine, in default of agreement. The expenditure of any capital during this period is to be subject to the consent of the Board of Trade, and will be deducted from the price payable to the Companies when the actual purchase takes place.

Further clauses preserve the rights which the Corporation of London, the Camberwell Borough Council, and the Lambeth Borough Council now have of purchasing the Companies in their areas prior to 1931.

London (Westminster & Kensington) Electricity Supply Bill

This Bill, although carrying out the same objects as the London Electric Supply Bill, differs somewhat in its clauses, mainly owing to a technical difficulty which prevented an instruction being moved in the House constituting the London County Council the purchasing authority in lieu of the local authorities concerned. Instead, an instruction was moved binding the Companies concerned in the promotion not to oppose any legislation to this effect in the future. Thus, although the London County Council is definitely constituted the purchasing authority of nine of the London Companies in 1931, the question of purchase in the present Companies areas is held open for future legislation. Further, one or two of the Companies of the previous Bill supply in the areas affected by this Bill; thus, some of the Companies in Westminster, for instance, are now purchasable, if the Bills go forward, by the London County Council, and, as matters stand at present, the remainder will fall into the hands of the Westminster City Council unless Parliamentary powers are given to the County Council to be substituted for the Westminster City Council. Beyond these matters, the two Bills are identical, with the exception of certain verbal alterations necessary owing to the altered conditions in the areas supplied by the two sets of companies.

Needless to say, many amendments were asked for by various opponents of the Bills, but the Committee, having laid down, so to speak, a certain policy in dealing with them, refused to depart from it, although it must be said that the attitude taken up at times was somewhat inconsistent.

L.C.C. Report on the London Electric Supply Bill.

As the result of the decisions of Sir Luke White's Committee, the Parliamentary Committee of the London County Council has issued a further report, in which they condemn the attitude of the House of Commons Committee towards the Council.

Dealing first with the instruction, constituting the London County Council the purchasing authority, the Committee state that the first question to be dealt with arose in regard to the interpretation of the words "on equitable terms" contained

Digitized by Google

in the instruction. It was contended on behalf of the companies that the House of Commons in passing the instruction had contemplated the safeguarding of the companies interests, and in support of this view reference was made to a certain interview which took place between representatives of the companies and the President of the Board of Trade. The Committee were previously unaware that any such exchange of views had taken place, and for the Council it was pointed out that not only was the companies' contention contrary to the Council's interpretation of the instruction of the House, but that the speech of the President in the House of Commons in the debate on the instruction strongly supported the Council's view that the instruction contemplated safeguards for local authorities whose rights might be affected. The paragraph in the speech is as follows:—"In the opinion of the Government the consolidated rights should be vested in the London County Council, after giving to the local authorities full opportunity to be heard in the interest of their ratepayers and their local claims to be fully appraised and adjusted." The local authorities supported the Council's view of the matter, and some discussion ensued, during which counsel for the Council (Mr. Freeman, K.C.) objected to any reference to the interview with the President on the ground that, if any views were held by the President other than those which could be gathered from his speech in the House, they should be placed before the Select Committee in the regular way by a representative of the Board of Trade. In the result, however, the chairman gave his ruling on the point in the following terms:—"The equitable terms can only have referred to the companies themselves as between the companies and the London County Council," and he added that this was the view of the Committee. This decision had a most important bearing on the subsequent proceedings of the Committee. The companies thereupon produced their clauses to give effect to the instruction.

The local authorities supported the Council's method of giving effect to the instruction of the House, but the companies most strongly objected thereto, and although the very onerous character of the companies' proposals was explained to the Committee, including the fact that whilst leaving the terms of purchase absolutely indefinite they departed entirely from the general law laid down in the Electric Lighting Act, 1888, the Committee decided to adopt the purchase clause proposed by Mr. Balfour Browne, K.C. (for the companies), with an alteration from ten years to three years, as the time of notice. (This clause is given in full above.)

The Committee also adopted, in face of the Council's strong objection, the proposal of the companies to require the Council to finance them during the years immediately before purchase. An obligation of this kind is, so far as the Committee are aware, entirely unprecedented. There would be no reasonable objection to an enabling power of this nature being given to the Council to advance money on agreed terms, but the clause put forward by the promoters makes it incumbent on the Council to lend money to meet the demands of the companies for any expenditure which the Board of Trade may decide to be reasonable. A proposal such as this, the report points out, which compels a local authority to lend an indefinite amount of money without full and adequate security for the payment of interest and principal is a very serious one, and should be opposed. The Committee disallowed a proposal to compel the Council to purchase the Willesden station of the Metropolitan Electric Supply Co., and preserved to local authorities their special powers of purchase exercisable before 1931.

The decisions of the Committee result, therefore, in the obligation being placed on the Council to purchase all the undertakings at the same time if it purchases any; the companies to have three years' notice instead of practically no fixed term of notice as at present; and the method of arriving at the purchase price of the undertakings is left entirely open to the arbitrator, with the reservation that the companies are in no case to receive less than the price which would have been payable under section 2 of the Act of 1888, and in the case of the City undertaking of the Charing Cross Company, that company is to receive a price not less than a price arrived at upon the basis of the very special terms above set out.

In view of the enormous financial transaction which would be involved in the carrying out of the purchase of the companies at one and the same time, the Council asked the right to discharge the purchase money by the issue of stock. The Committee, however, refused to allow the Council to discharge the purchase price wholly by the issue of stock, and reserved to the companies the right to the payment of one-half of the purchase money in cash. Further, the Committee declined to insert any power to enable local authorities to re-purchase distribution works from the Council, a matter to which the Council has attached considerable importance, particularly in view of the magnitude of the work which would be involved in carrying on the whole of the undertakings if purchased by the Council.

With regard to the amendments submitted by the Council as to the carrying out of street works and of its property, the Committee inserted some of the amendments desired, but in two important particulars at the instance of the local authorities, led by counsel for the City of Westminster, declined to insert the amendments desired, and also refused to allow the Council to have such protection in regard to the companies' operations as had previously been accepted by the companies. In this decision the Committee not only entirely depart from the established practice as embodied in the provisional orders relating to London electric supply, but refuse to the Council such rights as in the Bill they have allowed to the Middlesex County Council.

The Council will receive with deep regret the conclusions above set out. The Committee state they had hoped that the proceedings before the Committee would have resulted in the passing of a Bill dealing in a satisfactory way, not only with the question of linking up, but also with the difficulties of the question of purchase, which have so long been foreseen. As the Bill now stands, there will be little, if any, difference of opinion that in the interests of the public the present position of purchase, unsatisfactory though it may be, is preferable to the extraordinary departure contemplated in the Bill from the recognised principles governing the matter. It would be a matter for regret, however, if the present opportunity of removing some of the difficulties in connection with the supply of electricity in London by the Bill is to be entirely lost, and the Committee think the Council should endeavour to obtain therein such amendments as may make it compatible with the public interest. The Committee therefore point out that every endeavour should be made during the progress of the Bill to secure the following amendments:—(1) That the undertakings of the companies shall be purchasable under the provisions of section 2 of the Electric Lighting Act, 1888, except in the case of the undertaking of the Charing Cross Company within the area of the City of London. (2) That, in the case of this last-mentioned undertaking, it shall be purchasable on Electric Lighting Act terms, plus a consideration in respect of the loss which the company may sustain by reason of purchase taking place in 1931 instead of 1941. (3) That an enabling power for the Council to advance capital to the companies after notice of purchase has been given shall be substituted for the obligatory power now in the Bill. (4) That the Council should be entitled to discharge three-fourths and not merely one-half of the purchase money by the issue of stock. (5) That the Council and the local authorities may be empowered to agree as to the purchase by such local authorities from the Council of so much of the distributing systems of the undertakings purchased by the Council as may be within their districts. (6) That the usual powers for the Council with regard to street works be inserted in the Bill.

The following recommendation is attached to the Report:—That the Parliamentary Committee be authorised to take all steps necessary to secure that the amendments desired on behalf of the Council shall be inserted in the London Electric Supply Bill, and to prevent the Bill from passing into law in its present form.

In this connection we may point out that Mr. Rupert Guinness, Mr. Acland Allen, Mr. Walter Guinness, Mr. A. C. Morton, and Mr. B. Cooper have given notice of their intention to move the rejection of both Bills on third reading.

DEPUTATION TO BOARD OF TRADE.

On Thursday a deputation representing fifteen Metropolitan Borough Councils and thirteen local authorities owning electricity undertakings outside the County of London waited upon the President of the Board of Trade. The proceedings were private, but an official report has been published. The deputation was introduced by the Hon. Claude Hay, M.P., who stated that the deputation had two objects in view—namely, to ask the President to assist in the passing of the later stages of the London Electric Supply Bill, and also to reintroduce into Parliament the Electric Supply Bill, which was introduced by the Board of Trade in 1906, and in several subsequent sessions, so as to enable undertakings to give and take supplies of electricity in bulk.

Mr. Winston Churchill, in reply, said that he was pleased to find that at last there seemed to be some general agreement on the question of the necessity for improving the conditions of the electrical supply in and near London. On the question as to the advisability of undertakings being allowed to link up their systems there could be no doubt. He referred with satisfaction to the action of Sir Luke White's Select Committee in having inserted in the London Electric Supply Bill provisions consolidating the powers of purchase in the hands of the London County Council, and for enabling local authorities, as well as companies, to link up by mutual agreement. At the same time, it was of importance in the public interest that the companies should not be entitled to make any claim, on their undertakings being purchased, in respect of goodwill or other similar considerations. The Bill now before the House of Commons related to the County of London only, and it would be necessary for the Board of Trade to supplement that scheme, if it became law, by reintroducing the Bill referred to by the deputation, which would facilitate the linking-up of undertakings outside the Metropolis with the linked-up system created by the Bill now before Parliament.

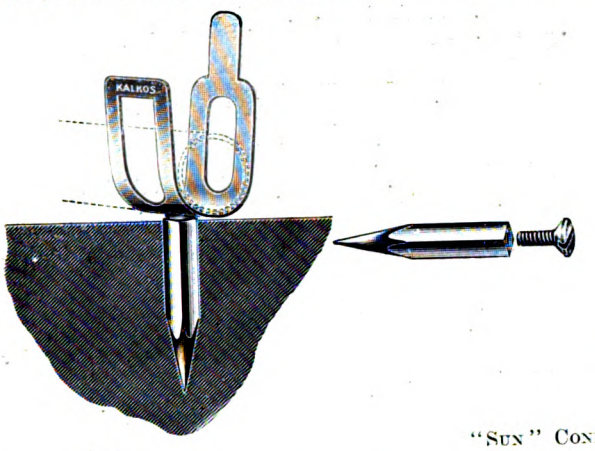
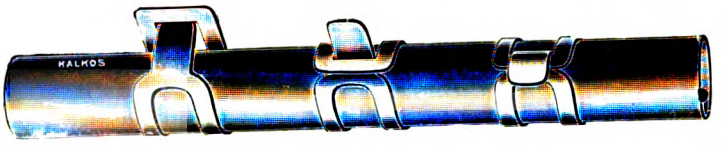
CATALOGUES AND PAMPHLETS RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering"].

CLIPS FOR FIXING CONDUIT.—The Sun Electrical Co., Ltd., of 118-120 Charing Cross-road, London, W.C., have sent us a leaflet relating to a neat "buckle" clip for fixing conduit, and they have also sent us a sample. The clip is of tinned brass, and its shape and the method of using it are clearly

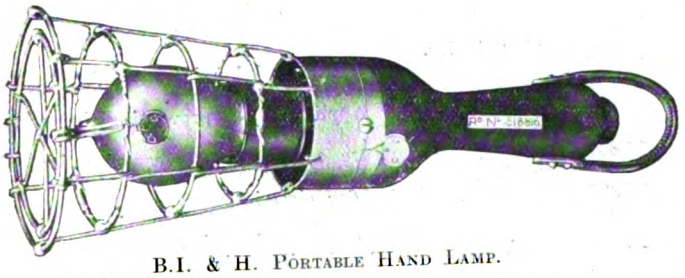




"Sun" Conduit Clip and Dowel Pin.

seen in the accompanying illustrations. Where the tubes are to be fitted to wooden surfaces, a small wooden screw may be used in place of the dowel pin and screw seen in the first illustration; but for use on brick or hard walls, the steel dowel pin and metal screw shown form a very convenient method of fixing. The pin is simply driven into the wall by a few blows with the hammer, and the clip is fixed to it by the screw, the dowel pin being tapped to take this. When the clip is placed round the tube and the tongue bent back, as seen in the second illustration, a very firm hold is obtained. The prices of the clips and dowel pins are extremely moderate.

PORTABLE HAND LAMP.—A leaflet from British Insulated & Helsby Cables contains particulars of the new form of hand lamp illustrated. This lamp was designed from the results of



B.I. & H. Portable Hand Lamp.

experience contained in the report of Mr. G. Scott Ram, H.M. electrical inspector of factories (see Electrical Engineering, July 23rd, page 137), and embodies all his recommendations. The principal features are: high insulation between brass lampholder and cage; first-rate mechanical construction throughout; screws fixing cage provided with wire holes for sealing, and cage fitted with a hinged lid, which may be sealed to prevent removal of lamp; substantial polished hard wood handle, with hole suitable for workshop flexible, edge rounded to prevent injury to flexible, and provision made for binding braiding to handle.

ARC LAMPS.—The new show card issued by the Gilbert Arc Lamp Co., of Chingford, with its quiet and harmonious colouring and simple, straightforward design, is a relief compared to many so-called "artistic" productions. It also partakes of the nature of a price list as well as an advertisement, and contains well-arranged particulars, as well as prices and illustrations of the company's well-known enclosed and flame arc lamps. Copies will be sent to any electrical contractors mentioning Electrical Engineering.

DYNAMOS AND MOTORS.—We have received a copy of the latest catalogue of Messrs. Morris-Hawkins, Ltd., of Dagenham, Essex, which relates to their standard lines of direct- and alternating-current dynamos and motors. The outputs listed vary from ¼ to 100 h.p., with a wide selection of speeds, but the firm manufactures machines up to outputs of 250 h.p. Variable-speed motors and machines for dealing with heavy overloads for short intervals are fitted with interpoles. Besides the standard lines of protected, enclosed ventilated, and totally enclosed machines, the catalogue contains particulars of back-geared motors, worm reduction gears for transmitting from 1 to 20 h.p. and with ratios of from 10 : 1 to 60 : 1, motor starters, balancer sets, and two- and three-phase motors. Messrs. Morris-Hawkins ask us to mention the fact that the works are under entirely new management, and that they can give prompt delivery of all machines up to 30 h.p., which are supplied under full guarantee for twelve months.

ELECTRIC CRANES.—A new catalogue of hand and electric cranes has been issued by Messrs. Adamson, Ramsbottom & Co., Ltd., of Birkenhead. A considerable number of illustrations of cranes, capstans, &c., of various types are included, which serve to give an idea of the large range covered by the productions of the firm of this class. A glance at these illustrations shows evidences of care in the designs, and the endeavour has been to produce patterns suitable for everyday hard usage, in which complications are avoided as much as possible.

ELECTRIC SUPPLY.—An attractive pamphlet is being issued by the South Metropolitan Electric Light & Power Co., giving a short historical sketch of methods of lighting leading up to the great possibilities of the tungsten lamp, which should be very useful in stimulating interest in electric lighting and spreading the knowledge of the fact that expense can no longer be urged as an argument against its adoption.

HEATING AND COOKING APPLIANCES, GLASS SHADES.—Two recent leaflets, copies of which will be sent to anyone mentioning Electrical Engineering, have been issued during the week by Messrs. Johnson & Phillips, Ltd. One deals with heating and cooking apparatus, and comprises lamp radiators, kettles, saucepans, urns, plate warmers, &c., while in the other are listed some of the simpler patterns of glass shades for incandescent lamps.

THREE-PHASE MOTORS.—Two well arranged lists are to hand from Mr. G. Wütrich, of Oswaldestre House, Norfolk Street, Strand, who represents the British Department of the Oerlikon Co. These deal with three-phase squirrel cage induction motors, and together cover a range from ⅛ to 85 h.p. for any voltage between 110 and 500 volts at 50 cycles.

BOOK REVIEWED

British and Foreign Hardware Trades. Guide to the Engineering, Steel, and 394 pages. 11 ins. by 7½ ins. (London: Adolphe Francis.) 10s.

This directory forms one of the series of guides to various trades published since 1877 by Mr. Alexander Lamb, and is being produced in precisely the same style by the present publishers. The book is divided into four sections, the first and larger comprising machinery, tools, metals, minerals, railway plant, &c.; the second, electricity, telegraphy, "galvanism," &c.; the third, ordnance, arms, ammunition, &c.; and the fourth, ships, boats, and their tackle, &c. The headings of the various sections are printed in English, French, German, and Spanish, in order to render the sphere of influence of the book practically international, but we are sorry to say that the translations into other languages of the subject-matter headings show a complete lack of acquaintance with foreign technical terms, especially as regards the German in the electrical section. This could easily be remedied in a future edition. Arc lamps, for example, are never called *Elektriches arc lampen* in German, but invariably *Bogenlampen*.

King's College Engineering Society.—The fifteenth annual dinner was held at the Trocadero, London, on Saturday, Sir W. H. Preece, K.C.B., F.R.S., presiding.

Electric Power for Madrid.—There are a number of small steam generating stations in and around Madrid, but several schemes are on foot for supplying cheap power generated at water-power stations. A company, called the Hidroelectrica Espanola, with a capital of £475,000, has been established, and has acquired water-power to the value of 42,000 h.p. on the rivers Jucar and Tagus. A power station with a capacity of 24,000 h.p. will be commenced shortly. Some 8,000 h.p. will be transmitted to Madrid, and 4,000 h.p. to Valencia. Another company has acquired a fall yielding from 8,000 to 18,000 h.p. in Guadalajara, some 44 miles from Madrid.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Nov. 26th, 1908

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

1907 Patents

17,743. **Electrolytic Deposition on Vitreous Surfaces.** Q. Marino. In order to render a vitreous, porcelain, or earthenware surface conductive for electrolytically depositing a metal on it, it is, according to this invention, first roughened, and a solution, in hydrofluoric acid, of the substance obtained by mixing cuprous oxide with nitrate of silver is then applied to the surface. By dusting the wet surface with powdered copper and zinc, the silver and copper fluorides are reduced, and a thin conducting film of silver and copper is obtained. This film is then polished. Three claims.

23,988. **Tungsten Compound.** F. Harrison and C. H. Dorman. This specification describes an organic compound of tungsten, which is obtained by reducing tungstic acid at a temperature of about 400° to 500° C. in the presence of hydrogen and an organic vapour such as alcohol. The product consists of 97 to 98 per cent. tungsten, 2·5 to 1·0 per cent. carbon, and 0·4 to 1·5 per cent. hydrogen; it is a conductor of electricity and heat. The same product can be obtained by boiling finely divided tungsten powder with alcohol. Four claims.

24,283. **Welding of Aluminium.** M. U. Schoop. An improvement in processes of welding aluminium, which consists in using a flux produced by adding fluorides of calcium, potassium, or boron to a mixture of chlorides of alkali metals. One claim.

24,343. **Electric Signal Lamps.** C. W. Cox and The Edison & Swan United Electric Light Co., Ltd. When electric lamps are employed for signalling at sea by means of flashes of short and long duration, the speed of signalling is limited on account of the time taken by the filament to come to full brilliancy and to cool down respectively. If a shutter is employed, the inertia of the shutter causes similar trouble. To increase the speed of signalling, the use of a vacuum tube is proposed in the present specification, and a self-contained weather-proof lamp, consisting of one or more vacuum tubes, and a transformer for raising the low potential supply voltage to the necessary high potential, is described. Six claims, four figures.

24,404. **Electromagnetic Coupling.** The Sunderand Forge & Engineering Co., Ltd., and W. Blair. An electromagnetic clutch or coupling for insertion between the driving motor and the gear or winding drum of electric cranes, hoists, and winches is described in this specification. It consists of a short-circuited armature mounted on the shaft of the driving motor, and a field system fixed to the winding drum or driving gear. The field system is separately excited from any available source; by varying the strength of the field, the pull of the clutch can be varied. Further, by reducing the strength of the field, the load can be lowered, although the driving motor is running in the opposite direction. Two claims, one figure.

25,842. **Automatic Transformer Switch.** J. T. Irwin, W. E. Robson, and J. L. Cook. This specification covers an automatic switch for auto-transformers. The switch in the primary circuit of the transformer is closed by a solenoid in series with the secondary circuit, one terminal of the secondary circuit being connected to the primary circuit on the supply side of the primary switch. On closing the secondary circuit, a small current flows through the solenoid and closes the primary circuit. The switch can be opened by gravity or by any other method. Three claims, three figures.

1908 Patents

3,049. **Cable Connector.** H. D. How and W. W. Partington. This invention relates to an improved form of cable connector which consists of a metal tube split longitudinally into two halves, the ends being tapered and screw-threaded for the reception of nuts. On tightening up the nuts, the two halves of the tube grip the cable and give a good electrical and mechanical joint. One claim, two figures.

6,605. **Lamp Globe Gallery.** A. Morrison. A lamp globe gallery, in which the usual screws are replaced by spring buffers, is described in this specification. The pins, which bear against the glass, can move backwards against the springs, and expansion of the glass is thus permitted. One claim, four figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

1907 Patents

20,223, "Z" Electric Lamp Syndicate (*Zerning*). Manufacture of filaments.
22,131, British Thomson-Houston Co. (*Allgemeine Elektricitäts Ges.*). Motor control.
23,450, Schattner & Amberton. Prepayment electricity meters.
24,729, Taylor. Brakes for tramway vehicles.
24,894, Slaughter & Harrison. Electrical measuring instruments.
25,109, Mortier. Ventilating-fans.
25,202, Barbary. Apparatus for ozonising liquids.
25,309, Felten & Guilleaume Lahmeyerwerke Akt.-Ges. Dynamo-electrical machines.
25,345, Winterburn. Permanent way of tramways.
25,589, Reinhardt & Johnson. Ceiling rose.
25,815, Collings & Hirst. Lamps and fittings.
25,953, Turner. Switches.
26,098, Davies & Davies. Brakes for railway vehicles.
27,171, Ewart. Electric water-heating apparatus.
28,132, Tate. Storage battery plates.
28,483, Stevens. Field magnets for obtaining rapid excitation.

1908 Patents

762, Mallman. Steam turbines.
1,203, Wyndham. Telegraphic transmission of photographs.
1,503, Chamberlain & Hookham, Ltd., & Holden. Electricity meters.
1,918, Parsons. Turbines.
2,074, Chaudoir. Electrically-controlled lifts, hoists, and cranes.
2,103, Cutler, Wardle, & Co., & Wardle. Electric incandescent lamps.
2,197, Moore. Lamp suspender.
2,498, Burt. Magnetic separators.
4,608, Suter. Holders for electric lamps.
4,844, Scheller. Apparatus for determining the damping and frequency of electric oscillations.
4,867, One Year Electric Clock Co., Grundke, & Lazarus. Automatic electric winding apparatus for clocks.
5,017, Harrison (*Electric Railway Improvement Co.*). Electrodes for welding, soldering, or brazing.
5,416, British Thomson-Houston Co. (*General Electric Co., U.S.A.*). Filaments for electric lamps.
5,691, Schürch & Himmel. Continuous or alternating current generators.
5,708, Showell & Harris. Shades for electric lamps.
5,859, Taylor. Alternating current relays.
9,077, Lake (*Schröder*). Armouring for insulated conductors.
9,648, Barbezat. Steam and gas turbine.
11,512, Siemens Bros. Dynamo Works, Payne, & Schupp. Motor starter.
12,275, Eastman & Warne. Electrical heating-apparatus.
12,644, Girdlestone & Thorkelin. Arc lamps.
13,930, Barker (*Walker*). Appliances for preventing the creeping of railway rails.
14,850, Trenzen. Manuacture of plastic masses of oxide of tungsten.
15,994, Frauenlob. Shades for electric lamps.
16,096, Siemens & Halske Akt.-Ges. Telephone installations.
16,272, Belin. Apparatus for reproducing pictures at a distance.
17,493, Wolhaupter. Insulated railway joints.
18,458, British Thomson-Houston Co. (*General Electric Co., U.S.A.*). Electric heating devices.
18,461, British Thomson-Houston Co. (*General Electric Co., U.S.A.*). Commutating poles.
18,880, Stephens. Manufacture of magnetos.
19,889, Siemens-Schuckertwerke Ges. Repulsion motors.
21,468, Allgemeine Elektricitäts Ges. Rotary pumps.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

1908 Patents

5,040, Planchon. Metallic filaments for electric lamps.
9,876, De Sainte-Claire. Variable-speed gear for electric automobiles.
9,877, De Sainte-Claire. Variable-speed gears.
23,007, MacGahan. Manufacture of electric conductors.
23,602, Hallock. Controlling devices for motors.
23,716, Livingston & Smith. Man-holes of conduit systems.
24,259, Christensen. Lightning conductor.

Expiring Patent

The following patent expires during the current week after a life of fourteen years:—

23,581 of December 4th, 1894. **Electrically Controlled Steam Whistle.** W. P. Thompson (*G. J. Schoeffel*). An electrically operated steam whistle, in which the hand and electric operating devices do not interfere with each other, although acting on the same valve. An electromagnet embodied in the whistle case opens an auxiliary valve, which admits steam to a small cylinder. The piston in this cylinder operates the whistle valve.

Digitized by Google

LOCAL NOTES

ABERDEEN: *Electrical Exhibition.*—Arrangements are to be made for holding a local electrical exhibition in February or March next.

ACTON: *The Supply from the Metropolitan Co.*—A special meeting of the Council has been held to consider the revised terms offered by the Metropolitan Electric Supply Co. to the Council as a result of a conference between the two parties. The new terms offered by the company are as follows:—"In lieu of the method of charges provided for in the agreement, the company will, during the years 1909 and 1910, accept payment for all energy supplied at the rate of £5 per KW. per annum of the maximum demand in each year, plus one-third of a penny per unit, provided that (1) electricity be again used for street lighting to the extent of not less than 110,000 units per annum; (2) proper sums be credited to the Electricity Department for any services rendered in connection with the sewage or other departments of the Council's works; and (3) the total payment to be made to the Council be not less than £4,200 per annum. The previous reduction made by the company represented a saving to the Council which during the 12 months ended June 30th last amounted to about £650. The effect of the proposed further reduction would, it is estimated, increase the saving to about £1,000 on the basis of the current year's business." In the result, a motion was carried:—"That the further consideration of the Metropolitan Electric Supply Co.'s proposals be postponed, and that the clerk enter into negotiations with the company for the latter to work the undertaking.

AUSTRALIA: *Tenders for Telephones.*—The *Melbourne Age* states that tenders are being invited from Australian firms only for 10,000 wall telephones, and that it is possible the order may be extended to 30,000 telephones, spread over a term of years, if it is seen that it is possible to establish this new branch of industry in Australia.

BARNSTAPLE: *Independent Report upon Electrical Undertaking.*—Mr. W. H. Trentham, Consulting Engineer of London, has been asked to visit Barnstaple, and to report upon the condition and working of the electricity undertaking at a fee of ten guineas.

BELFAST: *Expenses of Delegates.*—At the weekly meeting of the Tramways and Electrical Committee on Monday, Mr. Andrew Nance, the manager, reported that he had been in communication with the Municipal Tramways Association in regard to the surcharges recently made by the Local Government Board respecting the payments of the expenses of delegates to the meetings of that association. The organisation had taken the matter up, and had received a letter from the Local Government Board, in which it was pointed out that the surcharges in question would be remitted, but that at the same time there was no statutory enactment which authorised payments such as these from the rates, that Belfast was the only place in Ireland where tramways were owned by the municipality, and that if the Corporation wish to defray such expenditure out of the rates they must seek legislative authority. The manager added that the association still had the subject under their consideration.

BEXLEY: *Lighting and Tramways Undertaking.*—The Borough Accountant, in reference to the revenue account for the financial year to March 31st of the lighting and tramways undertakings, states that whereas the income was sufficient to meet all maintenance and working expenses and interest on loans, it was insufficient to provide for the whole of the amount payable to the sinking fund. A charge under this head has therefore been made upon the general district rate, and this has been approved by the Council.

BIRKDALE: *Electric Supply.*—The Clerk to the Ainsdale Council is in communication with the Birkdale District Electric Supply Co., with a view to the company applying for an Electric Lighting Provisional Order for Ainsdale.

BRIDGEND: *Taking Over of Power Station.*—The power station in Bridgend of the South Wales Electrical Power Distribution Co. was formally taken over by the Urban District Council last week. An estimated profit and loss account for the first year shows a deficit of £41, but certain economies which are contemplated in coal and water will, it is anticipated, easily transfer this into a profit for subsequent years.

BRIGHOUSE: *Agreement with Power Co.*—The agreement with the Yorkshire Electric Power Co., under which a supply of electrical energy in bulk will be given to the company, has now been sealed by the Council, although there was opposition to it by the Socialist members of the Council. The agreement will continue in force for 14 years, with the right of revising prices on the part of the Council at the end of the first seven years.

BRIGHTON: *Electric Tramways to Hove.*—The local papers report that the proposal by some private promoters to electrify the old Shoreham horse trams, and bring a line along Cromwell Road to connect with the Brighton Corporation system is not to be proceeded with for the present. The promoters in question appear to have changed their views as to the exact route to be followed, and will not apply for Parliamentary powers in the ensuing session, but will in all probability bring forward a revised scheme next year. Incidentally, it may be mentioned that the Hove Ratepayers' Alliance last week passed a resolution unanimously opposing the proposed scheme. As a matter of fact, the Alliance had appointed a sub-committee with a view to resisting the scheme, which, it was thought, was to be proceeded with this session.

Electric Heating and Cooking.—Mr. John Christie, the engineer and manager of the electrical undertaking, has reported having received from the Reason Manufacturing Co. an offer to provide and maintain suitable radiators at quarterly rentals of 4s. and 5s. respectively, according to the class of radiator selected, the Council to collect the money on on their behalf. Mr. Christie considered the proposal an excellent one, and pointed out that any other manufacturers or contractors who came forward with a similar scheme would also receive the same treatment. The Electricity Committee have agreed to the proposition.

CANADA: *Supply to Montreal.*—The Montreal Light, Heat & Power Co. have just put its new plant upon the Soulanges Canal into operation. The total capacity of the new plant, which is situated about 30 miles from the city, is 15,000 h.p.

CARDIFF: *Tramwaymen's Grievances.*—A deputation has waited upon the Tramways and Electric Lighting Committee regarding the action of Mr. Arthur Ellis, the Tramways Manager, in ordering tramwaymen who do Sunday duty to stand off one day of the ensuing week. It is contended that under an old agreement a fifty-four-hour week was guaranteed to the men, and that this was not to include Sunday work. The view of the men has been adopted by the Council.

CLYDEBANK: *Tramway Inspection.*—The tramways to the east of the Forth and Clyde Canal have been inspected by the Board of Trade.

DONCASTER: *Street Lighting.*—A proposal to light certain streets by gas has been rejected in favour of the use of electricity.

ENNISKILLEN: *Electric Lighting.*—The Council have received a number of offers from various firms for the installation of an electric supply installation.

EPSOM: *Electricity Undertaking.*—For the half-year ending September 30th, the receipts of the electricity undertaking amounted to £2,294, and the expenditure to £1,135. The receipts were £120 above, and the expenditure £136 below, the estimates. For the corresponding period last year the receipts were £1,910, and the expenditure £1,175.

FALKIRK: *Condition of Electricity Undertaking.*—A committee has been appointed to inquire into, and report upon, the working of the electricity undertaking.

FOLKESTONE: *The Tramway Bill.*—The Folkestone Chamber of Commerce has passed a resolution urging the Corporation to oppose the Bill of the National Electric Construction Co., which proposes to substitute overhead wires for the surface contact system originally proposed.

GLASGOW: *Proposed Tramway Extension.*—A deputation has waited upon the Extensions Sub-Committee of the Corporation Tramways Committee in opposition to the proposal to construct a tramway in University Avenue.

GOOLE: *Electric Lighting Order Revoked.*—The Board of Trade have revoked the Goole Electric Lighting Order, 1901.

HOUNSLOW: *Street Lighting.*—At the last meeting of the Council it was moved that in view of the Local Government Board inspector's remarks at the recent inquiry, the work in regard to the conversion of certain street gas lamps into electric lamps be postponed until after the inspector's report had been received. This was negatived, however.

INDIA: *Simla Water Power Scheme.*—The *Indian Trade Journal* of November 5th states that arrangements have been made for beginning work on the Simla water power electric scheme, and it is hoped to have 700 horse-power available early in 1911. The remaining 1,300 horse-power, for which the scheme provides, will be supplied when the demand for it arises. The site is some 14 miles from Simla, where the Nautikhud stream will be taken by a 6 by 3 ft. flume 12,000 ft. long into a tunnel 1,000 ft. long, and thence by a 550-ft. drop into the Sutlej river, where the turbines will be placed.

KIRKCALDY: *Tramway to Dysart.*—A sub-committee has under consideration a proposed extension of the tramway system to Dysart.

LONDON: *London County Council: Highgate Hill Tramways.*—In connection with the Highgate Hill cable tramway, further Parliamentary powers will have to be sought in relation to certain street widenings, which it is estimated will cost £10,500. Difficulties have arisen between the St. Pancras Borough Council and the County Council in regard to the cost of these widenings, the St. Pancras Council contending that as they are necessitated solely for the purpose of the tramway, the whole cost should fall upon the County Council finances. On the other hand, the Islington Borough Council, who are also interested as a road authority, have agreed to bear part of the street widenings in question.

London County Council Tramways.—In connection with the laying of cable ducts required for the reconstruction of the

Digitized by Google

Loughborough Junction to Norwood tramways, the Highways Committee of the County Council report that the Post Office authorities have applied for permission to lay a cast-iron pipe in the same trench as the Council's ducts. This has been agreed to on the understanding that the Post Office authorities pay a proportion of the cost of opening the ground and filling in and reconstructing the surface according to the number of pipes or ducts laid by the Council and the Post Office respectively, and, further, that, where it is necessary for the Council ducts to be laid at a lower depth, owing to the presence of the Post Office pipes, the Post Office shall pay the full cost of the excavation involved.

Deptford: Tramways.—In connection with the tramways in the borough, the London County Council will undertake the widening of Queen's Road, New Cross Gate, at an estimated cost of £25,500, the Borough Council paying one-third.

Poplar: Lighting of Blackwall Tunnel.—For the lighting of Blackwall Tunnel, the L.C.C. is to take, on agreement for five years, a supply on the following terms:—Maximum load not to exceed 55 kilowatts; minimum number of units per annum, 301,000; price per unit, 0·885d. The Committee are advised that this rate will be profitable to the Borough Council, in view of the exceptional load factor of 60 to 70 per cent.

Electrolytic Disinfectant.—The agents for the manufacturers of the Council's electrolytic disinfectant plant recently submitted samples of fluid similar to that made in Poplar to Dr. Klein, the bacteriologist to the L.G.B., and he has reported that one ounce of the fluid to 150 ounces of water (or one ounce in nearly one gallon of water) would kill cholera germs in 2½ mins., and the fluid in the same proportion would kill typhoid fever germs.

Stepney: G.B. System.—In a report by the Works Committee, the remark in the report of the Traffic Branch of the Board of Trade to the effect that the introduction of the G.B. Surface Contact system in the Mile End Road became necessary owing to the refusal of the Council to consent to overhead construction, and to the impossibility of using the conduit system in the roadway in question, is taken exception to. The Works Committee emphatically deny that it is impossible to use the conduit system for the reason stated—namely, the existence of the railway tunnel—and state that the entire responsibility for the adoption of the G.B. Surface Contact system rests with the London County Council.

MANCHESTER: *Telegraph Poles.*—There is considerable opposition to a request by the Postmaster-General for permission to erect a number of telegraph poles in certain streets of the city. On a previous occasion the Highways Committee gave its consent to the Post Office authorities for the erection of 55 poles in certain back streets and passages, but when the proposition came before the Council, it was rejected by a large majority. It is now suggested that the proposed poles should serve the double purpose of carrying telegraph wires as well as the wires for a system of fire alarms. The Watch Committee, however, objects to any fire-alarm wires being overhead.

Damages for Tramcar Accident.—Damages to the extent of £200 have been awarded to a passenger on a Corporation tramcar, who was injured through the car coming into collision with a baker's cart in Gorton Lane in April of this year. It is a curious fact that neither the car nor the baker's cart was damaged, but the passenger in question is alleged to have been thrown violently against a portion of the interior of the car, injuring his back, which has resulted in his being confined to bed ever since the accident.

NEWCASTLE: *Chairmanship of Tramways Committee.*—Sir Joseph Baxter Ellis, who had announced his intention of resigning the chairmanship of the Tramways Committee, has decided to remain in that position, it having been brought to his notice that his resignation was construed into a desire to quit a sinking ship. In making his announcement, Sir Joseph gave some particulars of the undertaking. At the present time the total capital expenditure was £1,174,745, and in addition to paying interest on capital, they had repaid loans to the extent of £201,680, whilst their reserve and renewals fund amounted to £75,650. Over and above all this, the sum of £12,000 has been contributed to the relief of rates.

NEWPORT (Mon.): *Halfpenny Tram Fares.*—A report by Mr. H. Collings Bishop, the City Electrical Engineer and Tramways Manager, on the question of halfpenny fares is distinctly unfavourable to the proposal.

NUNEATON: *Tramways.*—The scheme for providing electric tramways in Nuneaton is developing at the hands of private promoters, who announce that local capital will not be required. It is stated that a feasible scheme will be well received by the inhabitants.

ROCHDALE: *Tramway Supply.*—The Tramways Committee have asked the Electricity Sub-Committee to consider the question of reducing the price charged to the tramways undertaking. The Electricity Sub-Committee have reported that, from information regarding sixty-nine other towns, they gather that in forty-three of them the charges for tramway energy are higher than those in Rochdale. The present price in Rochdale is 1·13d. per unit, whilst the highest price mentioned in the list of towns referred to is 2·7d., and the lowest 0·62d. The Electricity Sub-Committee cannot see their way to recommend a reduction in the price now charged, but offer to forgo the sum of £236 which is paid by the Tramways Committee annually to the Electricity Department for establishment charges.

SOUTHEND: *Tramways to Hadleigh.*—The Corporation has replied to the Hadleigh Council that they cannot see their way to extend their tramway system into this district upon the basis of terms proposed by the Hadleigh Council.

ST. PETERSBURG: *Tramway Undertaking.*—It is stated that an offer has been made by a British Syndicate to purchase the municipal tramway system for £1,350,000. The offer is viewed favourably.

WALLASEY: *Tramways to Birkenhead.*—A proposal is under consideration for linking up Wallasey with Birkenhead, but whether it will be put into effect depends largely upon the attitude taken up by the local authorities concerned.

WEMBLEY: *Electric Lighting.*—The Council have received a communication from the North Metropolitan Electrical Power Distribution Co. that they cannot give any definite information as to the date of commencing work under the Wembley Electric Order.

WEYMOUTH: *Trackless Trolley System.*—Owing to the large amount of street widenings which will be necessary for the introduction of electric tramways, the trackless trolley system is being considered, as a substitute for the Great Western Railway Co.'s petrol omnibuses which now run in Weymouth.

New Generating Plant.—A 300-kw. steam turbine has been added to the generating plant in the power-house. The machine in question has been supplied by the Brush Electrical Engineering Co.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ALGERIA.—Information has been received at the Board of Trade to the effect that tenders are invited by the Bône Municipal Authorities up to January 15th for—(1) the construction and working of a central electric power station; and (2) the construction and working of an electric tramway. Copies of the projects, specifications, and notices (in French), together with a plan of Bône, may be seen by British firms on application at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, London, E.C.

ARGENTINE.—A decree has been issued authorising the Cia. del Ferrocarril Bahia Blanca y Noroeste to supply electric energy from their own works for lighting and power purposes in the town of Bahia Blanca. The company is granted rebate of duty up to 20,000 pesos for machinery and materials which it may be necessary to import for the extension of the works and the installation of apparatus, &c., in the town.

CANARY ISLANDS.—The steam tramway at Las Palmas has been sold to a Spanish Bank. The new proprietors intend to employ electric traction, and to erect a large power house, to reconstruct the roadway, and to purchase new rolling stock adapted to the new system of traction. It is, moreover, intended to extend the line to the town of Santa Brigida (5,000 inhabitants), situated in the mountains nine miles to the south-west of Las Palmas. The length of the present line is about four miles.

CARDIFF.—Tenders are invited for the supply, delivery, and erection of a 2,500 k.v.a. turbo-alternator, complete with surface-condensing plant and motor-driven auxiliaries. Particulars from the City Electrical Engineer and Manager, and tenders by December 18th (see an advertisement this week).

LONDON: *Hammersmith.*—The Council has taken up a loan of £10,000, payable in 20 years, for electrical purposes, and an application is to be made for a second loan of £9,085.

SHEFFIELD.—New plant to the extent of £7,000 is to be installed in the Kelham Island power station.

SOUTH AFRICA.—The *Cape Times* states that the Port Elizabeth Town Council has been authorised to raise a loan of £25,000 for the purpose of extending the electric lighting system of the town.

WALTHAMSTOW.—Tenders are to be invited by the Council for a supply of cable for the period ending March 31st, 1910.

Miscellaneous

AUSTRALIA.—The Melbourne City Council invite tenders for the supply of 33,000 incandescent electric lamps. Tenders by December 15th to McIlwraith, McEacharn & Company Proprietary, Ltd., Billiter Square Buildings, London, E.C.

AUSTRIA.—An expenditure of £250,000 is contemplated upon the development of the telephone service in Austria.

BAKU.—Tenders are invited, not later than January 24th, by the Municipal Council for the construction and working of a municipal tramway. It is proposed that the term of the con-

Digitized by Google

cession should be 42 years, and that the Council shall have the right to purchase the undertaking at the end of 22 years. The concessionaires must advance the Council £95,000 at 5 per cent., which will be redeemed during the term of the concession.

BIRMINGHAM.—Tenders are invited for the supply and delivery of various sizes of electric motors. Particulars from the City Electrical Engineer, and tenders by December 29th (see an advertisement this week).

EDINBURGH.—The Edinburgh and District Tramways Co. invite tenders for stores during 1909, including electric light supplies. Tenders to the Manager, 1 South Charlotte Street, Edinburgh, by December 7th.

LONDON: *London County Council.*—It is proposed to construct the authorised single line of tramways in Amherst Road between Mare Street and Dalston Lane, and in Dalston Lane between Amherst Road and Mare Street, in connection with the reconstruction of the Hackney Road to Stamford Hill tramways, for which arrangements will shortly be made. The cost of the work is estimated as follows: Track work, including special work, £5,400; rails, **£1,100.**

LOWESTOFT.—The Local Government Board has sanctioned a loan of £1,000 for free wiring purposes.

POWELL DUFFRYN STEAM COAL CO.—Tenders are invited for the supply of stores from January 1st, 1909, including india-rubber, asbestos, &c., steam tubes and fittings, and electrical goods. Tenders to the Directors of the Company, 101 Leadenhall Street, London, E.C., by December 7th.

RUSSIA.—The Perm Municipal Council invite offers for the construction of tramways.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—Alterations and additions to motor-bus garage, Redcliffe Road, East Ham. J. H. Ashley.

N.E.—Offices, Blackhorse Lane, Walthamstow, for Peter Hooker, Ltd., Blackhorse Road, Walthamstow.

S.E.—Lewisham Hippodrome, Brownhill Road, Lewisham. Architect, W. L. Griffiths, Lincoln Chambers, Portsmouth Street, W.C.

Curing-house, Channel Row, Bermondsey. Builder, W. J. Dixon, 3 Blue Anchor Lane, S.E.

Enlargement of Sorting Office, Southwark. H.M. Office of Works, Storey's Gate, S.W.

W.—Additions to Empire Theatre, Leicester Square. Architect, F. T. Verity, 7 Sackville Street, W.

W.C.—Wesleyan hall, Great Queen Street, Holborn. Architects, Gordon & Gunton, Finsbury House, Blomfield Street, E.C.

PROVINCES.

BATH.—Additions City Technical College (£8,000). Architect, A. M. Green, 5 Princes Buildings.

BEDFORD.—Additions to workhouse. Architect, H. Young, 35 Maitland Road, Bedford.

BLACKHEATH (BIRMINGHAM).—Library (£1,730). Builder, W. Copper, 7 West Street.

BLACKPOOL.—Post office (£16,760). Builders, R. Neill & Sons, Broughton Lane, and Neill Street, Manchester.

BRISTOL.—St. Ambrose Church (£12,000). Architects, A. W. & V. Gough, 23 Bridge Street.

School for the Blind (£14,000). Architect, E. Gabriel, Orchard Street, Bristol, and 42 Old Broad Street, E.C.

School, Alexandra Park (£9,000). Architects, Rodway & Demming, 28 Baldwin Street.

School, Kingsdown (£7,500). Architect, W. Skinner, Edinburgh Chambers.

BURSLEM.—Technical Institute (£9,000). Surveyor, F. Bettany, Burslem Town Council.

CARDIFF.—Dock offices, Bute Dock (£20,000). Architect, E. W. M. Corbett, Bute Estate Office, Castle Street.

New premises for Cardiff Laundry Co. Architect, E. W. M. Corbett, Bute Estate Office, Castle Street.

Co-operative wholesale premises, St. Mary Street. Architect, F. Harris, Balloon Street, Manchester.

CHELMSFORD.—New Council school, Trinity Road. T. Dixon, Town Clerk, Chelmsford.

CHILVERS COTON (Warwickshire).—Council school (£8,419) for Nuneaton Education Committee. Architect, E. E. Shepherd, Nuneaton. Builders, G. Smith & Son, Chilvers Coton.

COVENTRY.—New schools (3,000 places). F. Horner, Secretary to Education Committee.

CROYDON.—Dyeing and cleaning works, Waddon Marsh Lane. Architect, R. G. Ellis, Clarendon Road.

ERITH (Kent).—Alterations to public offices (£675). Surveyor, H. Hind, Erith Urban District Council.

GLASGOW.—Tramway depôt at Newlandsfield. Surveyor, A. B. McDonald, Town Council.

GREAT YARMOUTH.—Offices for Great Yarmouth Port and Haven Commissioners at South Quay. Architects, Olley & Haward, Queen Street.

HANLEY (STAFFORD).—New premises, Market Square, for M. Huntbach & Co., Ltd., Drapers, Hanley.

HASLINGDEN.—Extension to secondary day school (£6,000). W. Musgrove, Secretary, Education Authority.

HULL.—Premises, Holderness Road (£795). Architect, A. Easton, 7 Land-of-Green-Ginger.

LEICESTER.—Additions to Town Hall. Architect, F. Hames, 14 Gray's Inn Square, W.C.

County school. Architects, A. E. & T. Sawday, 6 Market Place.

Premises for Stamford, Spalding & Boston Bank. Architects, Stockdale, Harrison & Son, 7 St. Martins East.

NORTHAMPTON.—School, Billings Road, (£20,000). Architect, H. Norman, 4 Wood Hill, Northampton.

NORWICH.—Residence, Unthank Road (£967). Architects, Morgan & Buckingham, 1 Upper King Street. Builders, G. E. Hawes & Son, Duke Street.

Pavilion at Isolation Hospital, Bowthorpe Road (£2,797). A. E. Collins, City Engineer, Guildhall. Builders, T. Gill & Son, Rupert Street.

NOTTINGHAM.—Additions to lunatic asylum. Lewis, City Architect, City Hall.

READING.—Enlargement of Royal Berks Hospital (£20,000). Clerk to the Governors.

SALFORD.—Boys' department at Wellington Street School. Architect, Mr. Broadbent, c/o Town Council.

UPTON VALLEY (TORQUAY).—Secondary School (£12,000). Educational Secretary, S. H. N. Lane, Torquay Town Council.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The Victorian Postmaster-General's department has accepted the following tenders: British Insulated & Helsby Cables, Ltd., Melbourne, 11 miles 52-pair telephone cable, at £246 per mile; 5 miles 208-pair telephone cable, at £535 per mile; 1½ miles 260-pair telephone cable, at £630 per mile. W. T. Henley's Telegraph Works Co., Ltd., Melbourne: 5 miles 26-pair telephone cable, at £147 5s. per mile; 12 miles 78-pair telephone cable, at £313 10s. per mile. Western Electric Co. (Aust.), Ltd., Sydney, 3 miles 156-pair telephone cable, at £402 per mile; 80,000 paper sleeves, at 2s. 6d. per thousand, £10.

BELFAST.—The tender of the British Insulated & Helsby Cables, Ltd., for trolley wire has been accepted.

DOVER.—The tender of the British Westinghouse Electric & Manufacturing Co. for an alternator at £533 has been accepted, subject to the sanction of the Local Government Board to a loan.

ERITH.—The tender of Messrs. Beadle Bros. for the supply of coal for the electricity undertaking, at 14s. 9d. per ton, has been accepted.

GLASGOW.—The Corporation has accepted the following tenders in connection with the tramway undertaking: Lead-covered and single-core cables, British Insulated & Helsby Cables, Ltd.; plumbers' fittings, John Glendinning & Sons; trolley poles, Mountain & Gibson, Ltd.; car brake chains, Weldless Chains, Ltd.

LEYTON.—The quotation of the Underfeed Boiler Co. to fit the second Stirling boiler with a mechanical stoker similar to the one already installed has been accepted by the Town Council at £417.

LONDON: *London County Council.*—The Stores Committee have accepted the tenders of the following for annual supplies:—Electric fittings, globes, and shades, Baxter & Caunter, estimated value of goods to be supplied, £53; G. Braulik, £31; the City Glass Co., £6; Dorman & Smith, £27; Elliott Bros., £57; Falk, Stadelmann & Co., Ltd., £14; the General Electric Co., Ltd., £50; A. P. Lundberg & Sons, £13; W. McGeoch & Co., Ltd., £95; Nettlefold & Sons, schedule of prices; Siemens Bros. & Co., Ltd., £40 (quantities not given for certain items); Smith Bros., £14; G. Straus & Co., Ltd., £16; Taylor & Co., £4; Verity's, Ltd., £7; W. White & Co., £48. Electric insulating materials, Baxter & Caunter, £1; British Electrical & Manufacturing Co., £184; British Insulated & Helsby Cables, Ltd., £17; British Westinghouse Electric & Manufacturing Co., Ltd., £7; W. Geipel & Co., £40; the General Electric Co., Ltd., £34; James North Hardy & Son, £163; D. Jaroslaw, £7; the Micanite & Insulators Co., Ltd., £96; G. Schultz & Co., £276; Siemens Bros. & Co., Ltd., £23; Taylor & Co., £12; A. Terry, £176; Verity's, Ltd., schedule of prices. Electric cables and wires, Callender's Cable & Construction Co., Ltd., £172; Hooper's Telegraph & India Rubber Works, Ltd., schedule of prices; Western Electric Co., £2,961.

London County Council.—The following tenders have been received for the execution of the roadwork and platelaying, exclusive of the supply of rails and special trackwork, in connection with the reconstruction, on the underground conduit system of electric traction, of the existing tramways from Prince of Wales Road, *via* Fortess Road and Junction Road, to the Archway Tavern, Highgate: John Mowlem & Co., Ltd., West-

Digitized by Google

minster, S.W. (accepted), £31,223; Dick, Kerr & Co., Ltd., Cannon-street, E.C., £31,493; A. M. Coles, Paddington, W., £33,128. The chief engineer's estimate, comparable with the tenders, is £32,771. A provisional sum of £2,500 is included in each of the tenders for alterations of pipes, mains, &c., the cost of which works cannot be more accurately estimated beforehand, and a similar sum is also included for any other contingencies which may arise.

Poplar.—The Borough Council have received the following tenders for the supply of steam, feed, and blow-down piping in connection with the erection of the new boiler at the electricity works:—E. Le Bas & Co. (accepted), £303; Babcock & Wilcox, £338; J. Spencer & Co., £357; Wilson & Co., £389; Stewarts & Lloyd, £444.

SALFORD.—The Electricity Committee have accepted the tender of Balcke & Co., at £12,344 for the supply and erection of water-cooling plant at the electricity works. The tender of B. Thomas for the electric lighting of Seedley Baths, at £459, has been accepted. The Tramways Committee have accepted the following tenders:—A. G. Brown, impregnating plant, £75; Hulse & Co., Ltd., car-wheel lathe, £626; Witter & Son, Ltd., automatic sprinkler installation, £1,495.

STOKE-ON-TRENT.—The tender of Messrs. Davis, Perrett & Co. for an oil eliminator has been accepted at £170.

WALTHAMSTOW.—The Council have accepted the undermentioned tenders for arc lamp carbons for the period ending March 31st, 1910:—The Sloan Electrical Co., Conradty carbons for 10 ampere lamps; Geipel & Lange, Conradty carbons for five ampere lamps and ordinary carbons; Siemens Bros., Ltd., and The Sloan Electrical Co., flame arc carbons.

WATFORD.—The Electric Lighting and Power Committee have recommended the Council to accept the following tenders, subject to the sanction of the Local Government Board for a loan: Turbo-alternator, British Thomson-Houston Co., £2,400; condensing plant, Isaac Storey & Sons, £966; switchboard panel, British Thomson-Houston Co., £86 10s.; economiser No. 2, E. Green & Sons, £402; fan engine, Ashworth & Parker, Ltd., £188; building flues and foundations, L. R. Ensor, £496. The Committee have recommended that the tender of Messrs. Ferranti, Ltd., for meters be accepted.

YORK.—The Electricity Committee have accepted the tender of Messrs. G. Barnitt & Co. for engineers' stores, and of Messrs. Hardy & Holgate for general stores during 1909.

APPOINTMENTS AND PERSONAL NOTES

Mr. G. C. Jefferyes, of the Inverness Post Office Engineering staff, has been appointed sectional engineer at Dundee.

Mr. J. Sarginson, at present employed as station foreman at the Liverpool Tramways Electric Power and Lighting Department at a salary of £220 per annum, is to be appointed assistant superintending engineer of stations at a salary of £250 per annum.

The Willesden Urban District Council have appointed Messrs. J. C. Johnson and J. D. Ravenscroft charge engineers to fill two vacancies.

A junior meters assistant is required by the Birmingham Corporation. Salary, £100 per annum (see an advertisement this week).

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £66 to £66 7s. 6d. per ton (last week, £66 10s. to £67 per ton).

ADAMS MANUFACTURING CO.—An exhibition of "Igranic" electric motor controlling apparatus is now being held at the premises of the Adams Manufacturing Co.'s agent, Mr. David Alexander, 43 Mains Street, Waterloo Street, Glasgow. The exhibition closes on the 12th inst.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The Amalgamated Radio-Telegraph Co. is to be wound up voluntarily. Mr. F. W. Pixley and Mr. H. Allen have been appointed liquidators.

Telegraph Traffic.—The submarine cable between Oran and Tangier was restored to working order on the 25th ult., and on the following day the cable between Zanzibar and Mombassa was also repaired. The Russian Government notified on November 26th that codes must be produced when sending or receiving telegrams in code. On the same day, no doubt owing to the political unrest, the land lines in Hayti were closed, and telegrams can now only be accepted for the coast stations, viz., Cape Haiti, Mole St. Nicholas, and Port au Prince, all of these places being cable stations. The land line *via* Batoum also suffered interruption on November 27th between Castamouni and Samsoun, while the El Arich route became inoperative between Lattaquie and Beyrouth, and between Alep and Beyrouth on the 29th ult. On November 30th the cable between Medan and Oleleh was again in working order.

COMPANIES' MEETINGS AND REPORTS

AMAZON TELEGRAPH CO.—At the annual meeting on Tuesday, the report and accounts, given in our last issue, were adopted.

BERLIN ELECTRICITY WORKS.—The report for the year 1907–8 shows that the undertaking is steadily developing. The number of consumers has been increased by 2,543, and the connected kilowatt by 17,538, or over 13 per cent. These figures are somewhat larger than the corresponding figures for the previous year. The payment to the City of Berlin amounts to approximately £250,000, of which £116,000 is the royalty of 10 per cent. which is due, and £134,000 is in the form of dividend. The gross profits for the year amounted to £733,000, which, after allowing for the above royalty, depreciation, and renewals fund, and other charges, leaves a net profit of approximately £362,000. Of this £18,000 is assigned to the reserve fund; £22,500 to the payment of dividends of 4½ per cent. on preference shares; £173,000 to the payment of an 11 per cent. dividend on ordinary shares; £134,000 to the City of Berlin, as above mentioned; and the remainder to the pension funds, bonuses, directors' fees, &c. An amount of £64,000 is carried forward.

GENEVA TRAMWAYS CO. (1906).—At the annual meeting held in London last week, the report and accounts given in our last issue were adopted. The chairman, the Hon. A. G. Brand, stated that negotiations were in progress with regard to a supply of power by the Geneva municipality, which it was hoped would be at such a price as to counterbalance the increased expenses of working the lines which had been brought about mainly by the increase of wages, &c.

ISLE OF THANET ELECTRIC TRAMWAYS & LIGHTING CO.—At the annual meeting on Thursday, the report and accounts given in our last issue were adopted. Considerable discussion took place concerning the affairs of the company, and it was eventually decided to appoint a committee of four shareholders to confer with the Board both with regard to the best means of raising new capital, and also concerning the affairs of the company generally.

LANCASHIRE POWER CONSTRUCTION CO.—At an extraordinary general meeting held in London on Friday, a resolution was passed authorising the raising of £150,000 for the completion of undertakings which have been commenced in various parts of Lancashire. The stock is to be offered upon favourable terms to the present shareholders.

SIEMENS-SCHUCKERT WERKE. G.m.b.H., BERLIN.—The report for the past year shows a net profit of £510,000 after extensive writings off, which is slightly larger than the corresponding figure for the previous year. Of this amount £450,000 will be absorbed in dividends, £40,000 will be paid out as bonuses, and £17,500 will be set aside for the management fund. The remaining sum will be carried forward. It is stated that the orders which have been received during the present business year do not materially exceed those of the same period last year. Among the tenders which have been accepted are two for the electrical equipment of two ships for the German Navy, now being built at Geestemünde and Hamburg respectively.

SINGAPORE ELECTRIC TRAMWAYS.—At the ordinary general meeting held last week, the report and accounts given in our last issue were adopted. Sir Frank A. Swettenham, chairman of the company, who presided, stated that when the tramways were first opened in 1905, regular provision was made for two classes of passengers. It was found, however, that the patronage given to the first class accommodation was insufficient to warrant the continued provision of it, and subsequently one class was substituted for two. During the past year, however, the General Manager has given further attention to the question, and has introduced a limited service of first class accommodation by reserving the two first seats on certain of the cars for first class passengers. With regard to the depression in trade in Singapore referred to in the accounts, the chairman stated that although this still continues, the Governor of the Colony had recently expressed the opinion that the worst had been reached, and that they might look for improvements in trade which must favourably affect the tramway business.

WELDLESS STEEL TUBE CO.—At the annual meeting on Tuesday, the report and accounts, given in our last issue, were adopted.

NEW PUBLICATIONS

Science Abstracts. November. Section A, Physics. Section B, Electrical Engineering. (London: E. & F. N. Spon, Ltd.) 1s. 6d. each.

"National Electric Light Association. Proceedings of Thirty-first Convention at Chicago, 1908." (New York: The Association.)

Wireless Telegraphy.—The Paris correspondent of *The Times* states that a Bill for putting into force the decisions of the Berlin Wireless Telegraph Conference of 1906 has been laid before the French Chamber.

MISCELLANEOUS CITY NOTES

BRUCE PEEBLES & CO.—The joint liquidators have issued a circular stating that the scheme of arrangement, outlined in our issue for November 19th, has now been sanctioned by the Courts, owing to the fact that no appeal against it had been lodged during the 14 days allowed for this purpose. The first directors of the new company are: Mr. Charles H. M'Euen, of Callenders Cable & Construction Co., Ltd.; Mr. B. M. Mountain, of Mountain & Gibson, Ltd.; Mr. Alexander Mackenzie, of Mackenzie & Moncur, Ltd.; Mr. F. E. Andrews, of Brush Electrical Engineering Co., Ltd.; Mr. C. J. Shiells, chartered accountant, Edinburgh; and Mr. A. W. Tait, chartered accountant, London.

COMPANIES TO BE STRUCK OFF REGISTER.—The following companies will be struck off the register at the expiration of three months, unless cause is shown to the contrary:—Hemsworth Electricity Supply Co. Home Counties' Electricity Supply Co., Hyde Electrical Manufacturing Co., and the Irish Electrical Agency.

MEXICAN LIGHT, HEAT, & POWER CO.—The annual meeting has been postponed until December 30th.

SOUTH WALES ELECTRICAL POWER DISTRIBUTION CO.—The *Stock Exchange Gazette* states that there is good reason to believe that the anticipations indulged in at the commencement of this year regarding the outlook for this company will prove to have been fulfilled when the accounts for December 31st next come to be made up. The profit and loss account, it is believed, has at length been established on a basis which represents at least a fair approximation to equilibrium between revenue and expenditure, whilst the general outlook is decidedly favourable. It would seem, therefore, that the extraordinary efforts of those who some eighteen months ago rescued the undertaking from a position which promised to become fatal, may now be regarded as having justified the attitude taken up by them at a critical period in the history of the concern.

Siemens Stafford Engineering Society.—The first annual conversazione of this society was held on Friday, November 20th, in the large hall of the Siemens Institute. The major portion of the staff of Messrs. Siemens Bros. Dynamo Works, Ltd., and a large number of local residents were present. A large number of scientific and engineering exhibits were arranged, and popular scientific lectures were delivered by Messrs. Catterson-Smith, Hey, and Pollard. Among the other attractions were a short vocal concert, and a sketch by the Siemens' Amateur Dramatic Society. Selections were given by the Siemens' Institute Orchestra during the evening.

OFFICIAL ANNOUNCEMENTS AND SMALL ADVERTISEMENTS.

Official Advertisements are charged at the rate of **9d.** per line (column width).

Small Prepaid Advertisements of Situations Vacant and Wanted, Plant for Sale or Wanted, &c., are inserted at the rate of **1/-** for the first 12 words and 1d. per word afterwards. Three insertions for the price of two. Advertisements can be received up till Wednesday morning first post.

Letters should be addressed to The Kilowatt Publishing Co., Ltd., 203-6, Temple Chambers, London, E.C.

TENDERS INVITED.

CITY OF BIRMINGHAM.

ELECTRIC SUPPLY DEPARTMENT.

To Contractors for Electrical Apparatus.

TENDERS are invited for the SUPPLY and DELIVERY of various sizes of ELECTRIC MOTORS required by the ELECTRIC SUPPLY COMMITTEE.

Applications for General Conditions, Specification, and form of Tender to be made at the office of the City Electrical Engineer, Mr. R. A. Chattock, M.I.E.E., 14, Dale End, Birmingham.

Before obtaining the General Conditions and Specification it will be necessary to deposit the sum of One Guinea, for which a receipt will be given. The amount of deposit will be returned after the Committee's decision, provided that the contractor shall have sent in a *bona fide* tender, and shall not have withdrawn the same.

The Electric Supply Committee does not bind itself to accept the lowest or any tender, nor will the Committee pay any cost in tendering.

All workpeople engaged on any part of the work, whether sub-let or otherwise, shall not be paid less than the minimum standard rate of wages current in the district in which the work or works may be constructed or executed, and no work shall be sub-let to persons not paying at least the minimum standard rate of wages in the said district. The tender of any person or firm paying to their workpeople less than the minimum standard rate of wages current in the district will not be accepted.

Tenders to be sent in under seal, addressed to the City Electrical Engineer, at the Electric Supply Department, Dale End, Birmingham, and endorsed on the outside "Tender for Electric Motors," not later than 12 o'clock noon on TUESDAY, December 29th, 1908.

R. A. CHATTOCK, M.I.E.E.,
City Electrical Engineer and Manager.

14, Dale End,
Birmingham.
December 3rd, 1908.

APPOINTMENT FILLED.

APPLICANTS for position of Installation Assistant at Belfast are thanked, and will please note that the position has now been filled.

APPOINTMENT VACANT.

WANTED, an Engineer having a practical acquaintance with modern electrical developments. Such engineers are in demand, and command large salaries. You can qualify at home, under experts, and by a unique system. Prospectus free, The British Correspondence School of Electrical Engineering. Dept. M., 36, Maiden Lane, Strand, London.

TENDERS INVITED.

CITY OF CARDIFF.

THE CARDIFF CORPORATION are prepared to receive Tenders for the supply, delivery and erection at their Generating Station for the following:—

1-2500 K.V.A. TURBO-ALTERNATOR

complete . . . with surface Condensing Plant and Motor Driven Auxiliaries.

Specifications and form of Tender may be obtained from Mr. Arthur Ellis, City Electrical Engineer and Manager, Central Offices, The Hayes, Cardiff, on payment of a Deposit Fee of One Guinea, which sum will be refunded on receipt of a *bona fide* tender.

The successful Contractor will be required to enter into the usual form of Agreement, a copy of which can be seen at my Office.

Sealed Tenders endorsed Turbo-Alternator to be delivered at my office on or before 10 a.m. Friday the 18th inst.

J. L. WHEATLEY,
Town Clerk.

City Hall, Cardiff.
1st December, 1908.

APPOINTMENTS VACANT.

CITY OF BIRMINGHAM.

ELECTRIC SUPPLY DEPARTMENT.

Appointment of Junior Meters Assistant.

APPLICATIONS are invited for the above post. Applicants must have had thorough training in the testing of Alternating Current Meters and be familiar with the best known makes; they must also be experienced in the connecting up of 3-phase 3-wire Meters on 5,000 volt Circuits.

Salary, £100 per Annum.

Applications must be accompanied by recent testimonials and forwarded to the undersigned not later than Tuesday the 15th inst.

R. A. CHATTOCK, M.I.E.E.,
City Electrical Engineer and Manager.

14, Dale End,
Birmingham.
December 3rd, 1908.

BOROUGH ENGINEER.—Electrical Engineer in Midlands has vacancy for premium pupil; lighting power and traction. Box, A 61, Electrical Engineering, 203, Temple Chambers, London.

ELECTRICAL ENGINEERING

All rights reserved.

Registered as a Newspaper.

No. 102 [Vol. IV., No. 24] THURSDAY, DECEMBER 10, 1908. [Price One Penny.

ELECTRICAL ENGINEERING.

The Engineering Journal of the Electrical Industry

Published every Thursday. Price **1d.**

SUBSCRIPTION RATES.

United Kingdom. 6s. 6d. per Annum.

Canada. 8s. 8d. per Annum.

Other Colonies and Abroad. 13s. per Annum.

Small prepaid Advertisements for Situations Vacant and Wanted, Articles for Sale and Wanted, &c., are inserted at the rate of One Penny per word, minimum One Shilling, three insertions for the price of two.

Official Notices and Technical College Announcements are inserted at the rate of Ninepence per line (column width).

Other Advertisement Rates on Application

Latest Time for Receiving

Letters for Insertion, *Tuesday first post.*

Small Advertisements and Official Announcements *Wednesday first post.*

Displayed Advertisements, *Tuesday first post.*

Corrections in Standing Advertisements, *Monday first post.*

All letters to be addressed to "Electrical Engineering," at the Editorial and Publishing Offices: 203-206, Temple Chambers, London, E.C.

Telegrams: "Circling, London." Telephone No.: 5509 Holborn.

Cheques to be made payable to The Kilowatt Publishing Co., Ltd., and to be crossed London and Westminster Bank (Temple Bar Branch).

Binding Cases for Vol. III. may be obtained, price 2s. each, post free 2s. 4d. Readers can have their volumes bound by their own bookseller; or they may send their numbers to us, carriage paid (with the reader's name and address), and a remittance of 4s. 6d. under separate cover. The volumes will then be bound and returned carriage paid to any address in the United Kingdom, or carriage forward to the Colonies or abroad.

"Electrical Engineering," although the Cheapest Electrical Paper (Price **1d.** weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

The new mountain railway near Bozen in the Tyrol, known as the Rittnerbahn, has some unusual and interesting features. It is partly a rack railway, and, whereas locomotives with shunt-wound continuous-current motors are used to take the cars up and down the steep gradient, the cars, which are equipped with ordinary series-wound traction motors, run by themselves on the horizontal portions of the line. The rack portion is on the Strub system. When descending the gradient, the locomotive motors return energy to the line. Power for working the railway is supplied over a three-phase line from a water-power station some twenty miles away, and is converted to continuous-current at 750 volts in a sub-station about half-way along the line. (Page 751.)

The report of the Committee appointed by the Municipal Tramways Association at the suggestion of Colonel Yorke, of the Board of Trade, has now been issued independently from that of the Committee of the Tramways and Light Railways Association, of which an abstract was published on page 647 of Electrical Engineering, of November 12th. Although in some way there is divergence in the points of view taken in the two reports, the final conclusions do not conflict. Both committees emphasise the importance of the human element, recommending the more thorough training of drivers, and realise the dangers of rails not properly cleaned; but while the Municipal Committee incline to the view that an ideal brake could be designed to meet all conditions, the report of the Tramways and Light Railways Association favours the consideration of each case separately. (Page 753.)

A letter appears in the Correspondence columns, calling attention to the organisation of opposition to the Miners' Eight Hours Bill by the Coal Consumers' Defence League.—Mr. A. M. Taylor contributes a communication relating to the use of storage batteries for the improvement of load factor, and criticises some of the statements in Mr. Lackie's recent Presidential address to the Glasgow Local Section of the Institution of Electrical Engineers.—A correspondent asks for the name of a manufacturer of glass boxes for storage batteries. (Page 755.)

A REVIEW appears in this issue of "High Speed Dynamo Electric Machinery," by Messrs. H. M. Hobart and A. G. Ellis. (Page 756.)

A VERY exhaustive Paper on transformers was read last week before the Manchester Local Section of the Institution of Electrical Engineers by Messrs. A. P. M. Fleming and K. M. Faye-Hansen, of the British Westinghouse Co. In the first part of the Paper, which was mainly theoretical, comparisons were drawn between the various forms of the core and shell patterns, the influence of size and magnetic property of core material upon efficiency was considered, and the theoretically most economical ratio between copper and iron losses under various conditions of load factor and price per unit was discussed. The latter part of the Paper dealt with a number of interesting practical points in connection with methods of cooling, insulation and mechanical construction of transformers. In the discussion which followed some further advantages of particular types were mentioned, and the influence on design and cost of the introduction of improved magnetic material was spoken of. It was pointed out that its advantages were not so marked in the case of low frequencies, as the rating in these cases was apt to be limited by the no-load current. (Page 757.)

AMONG the novelties described in short articles in this issue are a simple pattern of auto-transformers for metal filament lamps, an ingeniously designed reduction gear for motors, and an alternating-current lift controller. A notice is also given of a very complete exhibit of insulating materials at the recent Marseilles Electrical Exhibition. (Pages 761 and 762.)

THE Verein Deutscher Ingenieure, corresponding to the British Institution of Civil Engineers, has presented a memorial to the German Reichstag, in which an urgent appeal is made to reject the proposals of the Government relating to the taxation of electricity and gas. (Page 762.)

THE Board of Trade has refused to sanction the proposed transfer of the Bath Municipal Electricity Undertaking to the Bath and District Electric Supply Co. (Page 763.)

THE latest form of the Geipel "Rapidity" steam trap differs in some respects from the older design. A special self-adjustable pattern is made to the requirements of the Admiralty. (Page 763.)

A CONFERENCE is to be arranged between the promoters of the Holywood Tramways and the Belfast Corporation with regard to mutual running powers.—The petition of the Hove Corporation to the Board of Trade for a reduction in the prices now charged for electricity supply by the Company has been rejected.—The overhead tramway system of the London County Council from Brixton Road to Denmark Hill has been completed, and a through service is being maintained over the conduit system.—The Marylebone Borough Council have adopted the scheme of street lighting by Osram lamps given in our last issue. The cost is estimated at £8,650 compared with £8,818 now paid for gas.—The Malvern Council has decided not to consent to the introduction of the trackless trolley system.—The National Electric Construction Co. propose to use the overhead system on the tramway extension to Paignton, and have hinted to the Torquay Corporation their desire to substitute the trolley system for the Dolter surface contact system now in use.—The Electrical Committee of the West Ham Corporation again advise that the special contracts for power should not be produced as required by the Local Government Board Inspector, and the Town Clerk has been instructed to take the necessary steps for the protection of the Corporation's interests in the matter.—A conference of West London local authorities has been held in reference to the condition of the London United Tramways Co. track, and Sir Clifton Robinson has been invited to attend an adjourned conference on Monday next. (Page 765.)

Two 3,000-kw. turbo-generators are required by the Bradford Corporation.—The London County Council has sanctioned loans for electrical purposes as follows! Hampstead, £5,900; Stepney, £9,500.—The Woolwich Borough Council has completed a loan of £2,625 for electrical purposes.—A Local Government Board inquiry was held at Carlisle last week (£1,000), and inquiries are to be held as follows: Hereford (£8,000); Maidenhead (£3,500).—An application is to be made by the Birmingham Corporation for £92,000 for tramway purposes.—A loan of £12,400 has been sanctioned to the Liverpool Corporation for tramway purposes. (Page 766.)

THE report of the India Rubber, Gutta Percha and Telegraph Works Co. for the year to September 30th shows a balance available for dividend of £89,480. A dividend of 10 per cent. for the year is declared, and the balance of £51,980 is carried forward.—After meeting all charges, the accounts of the Manx Electric Railway Co. show a balance of £1,050 for the year to September 30th, which sum is carried forward. No dividend is paid on the ordinary shares.—Applications have been invited by the London Electrobus Co. for an issue of £40,000 6 per cent. convertible first mortgage debenture stock, and by the Monterey Light and Power Co. to an issue of £1,000,000 5 per cent. first mortgage debenture stock.—Statements have been issued by the board of directors of the Mexican Light and Power Co., and also by the committee of shareholders with regard to the proposed lease of the undertaking to the Mexico Tramways Co. (Page 768.)

THE annual dinner of the Birmingham Local Section of the Institution of Electrical Engineers took place last Wednesday. (Page 771.)

AMONG the specifications published by the Patent Office on Thursday last is one by the "Z" Electric Lamp Syndicate, in which a process for the manufacture of tungsten filaments is described. Means for dimming the lamps on a circuit controlled by an electrolytic prepayment meter, when the amount paid for has been consumed, is patented by E. Schattner and R. Amberton, and a field system for the dynamos of petrol-electric vehicles is described in a specification by W. A. Stevens. The British Thomson-Houston Co. have a patent for a modification in the known process of manufacturing metallised carbon filaments, and a specification by Siemens Bros. Dynamo Works, B. G. Payne and E. Schupp, relates to a type of motor-starter in which a step-by-step motion is obtained by means of a balance-wheel. Patents relating to heating apparatus, such as electric flat-irons, have been obtained by W. E. Eastman and A. Warne, and by the British Thomson-Houston Co. respectively. An application for amendment to a specification relating to electric power transmission systems for vehicles has been made by E. W. Hart and W. P. Durtnall. Among the expiring patents this week is one by Dr. Carl Kellner relating to electrolytic apparatus. Short abstracts of the above specifications are given in our Patent Record. (Page 772.)

THE Municipal Tramways Association has promptly followed the Tramways and Light Railways Association with the Report of its Committee on Tramway Brakes, and, from the abstract printed elsewhere, it will be found that there is no clashing between the general conclusions of the two committees. There is, however, some difference in the points of view adopted. The earlier report made a very thorough examination of the brakes available, their advantages and disadvantages, from which an intelligent choice can be made to suit given conditions; that now under discus-

Digitized by Google

sion rather looks forward to an ideal standard brake applicable to all conditions, and sets out what it should do. These two views are complementary, not contradictory. One matter in which the reports agree is the emphasis they give to speed control on gradients. the value of the track brake for such purposes, the importance of clean rails, and, failing the prevention of greasy rails, the importance of sanding apparatus. The municipal report rather suggests that greasy rails should be abolished altogether—an ideal condition very difficult and expensive to realise, whilst road materials, general traffic, and British weather, remain as they are. A distinctively municipal view is expressed in the first six proposals of our abstract, dealing with the breaking of regulations, working steep gradients, the employment of unfit men, insufficiently tested brakes, and insufficient inspection of braking equipments in the depôts. Reading these paragraphs an outsider will take them as reflecting seriously upon the competence either of the inspecting officers of the Board of Trade, whose duty it is to make safety regulations for every line, or that of the managers, whose duty it is to see that the regulations are strictly observed by a competent staff; and it is strange that a committee of tramway managers should have published such views. Reading between the lines, we believe that the true meaning is that many municipal managers are seriously interfered with in these respects by their committees, and the paragraphs mentioned are an appeal for the protection of the managers from such interference by an outside power. On either reading the publication appears ill-advised. The Municipal Tramways Association should be strong enough to protect its own managerial members, by means less disquieting to the public. The technical considerations are inspired throughout by striving after ideals, *e.g.*, that one gear should be used for all purposes, and that any failure or accident should cause an actual application of the brake. How this holds good in the case of the driver losing his head, or to wheel-skidding on greasy rails, is not obvious. It is easy to say what an ideal brake should do, but until it exists, it is more to the purpose to show how to make the best use of what there is, and it is here that the report seems to us most defective. Of a piece with the idealism mentioned is the suggestion that there should be a standard brake equipment applicable to all systems. To load a car designed, say, for the level roads of Southport with the braking equipment needed in hilly Halifax is not good engineering, from either the operating or the commercial point of view; nor can we agree that the quick-acting brake needed in the traffic of London or Manchester is required for inter-urban lines. The due fitting of braking equipment to the conditions is as essential as the due fitting of motor equipment, and the question of cost seems to have been forgotten. The recommendations that we can most heartily endorse are those of greater attention to rail cleaning, the use of track brakes for controlling speed on gradients, and the selection, training, and control of employees. The first and last are, or should be, in the hands of tramway managers themselves. The "practical result of the Committee's deliberations" is that a brake is desirable which has certainly not yet been invented, and which will do certain things that are truly rather difficult of attainment. The most important practical result of the Committee's investigations, in our view, on the other hand, is that given by the tests of track brake blocks, which show a remarkably high value for serrated cast-iron blocks. If this result is confirmed by further tests, the terrors of the greasy rail will be very materially diminished. The number and details of the tests tabulated and in diagram form appended to the report, show great industry on the part of the Committee, both as observers and compilers. Fortunately, they supplement those of the Tramways and Light Railways Association Report, and, taken together, the two sets form a mine of information representing the whole of our present knowledge on the subject, and showing where further research is required. It now devolves upon the Board of Trade to issue a set of regulations based upon the results of the investigations made by the two Committees.

The paper read by Messrs. A. P. M. Fleming and K. M. Faye-Hansen last week before the Manchester Local Section of the Institution of Electrical Engineers was a valuable contribution to the literature of the transformer, although, from the point of view of a Paper to be discussed in its entirety at a single evening meeting, perhaps it covered rather too much ground. The comparison of the different varieties of the shell and core pattern of transformer was interesting and thorough, although the final result, that there is little to choose between them, is a little disappointing. One of the most important points affecting the future of transformer design touched on was the tremendous influence which the introduction of alloy steels with low hysteresis quality is having on the size, and therefore the cost, of transformers of given output and efficiency; or, to put it in another way, on the efficiency of transformers of a given size and output. It is to be hoped, however, that these new brands of transformer plate, excellent though their hysteresis constant may be when new, will prove "non-ageing" in the sense of their hysteresis loop not increasing as time goes on, due to the prolonged heating to which the transformer is subjected on load, for it was certainly found in the early investigations of the subject by Ewing and others that the better the initial magnetic properties of the materials then obtainable, the worse was their lasting quality, so that often it paid better in the long run not to employ material which gave the best figure in the hysteresis tester. It was seen in the Paper, and more emphatically brought out in the discussion, that the advantage is not so high in the case of low-frequency transformers, as the limiting consideration is often the no-load current, and this calls more for a steel of exceptionally high permeability than low hysteresis. If the combination of the three qualities of low hysteresis, high permeability, and good non-ageing properties can be obtained, then the steel-maker will have conferred a lasting benefit on the transformer manufacturer, and indirectly on the station engineer.

It will be seen from an article which we publish on another page that the two great engineering societies in Germany, corresponding approximately to our Institutions of Civil and Electrical Engineers, are vigorously opposing the tax which the German Government proposes to put upon electrical energy. This is hardly to be wondered at. The proposal is to collect a tax of

Digitized by Google

5 per cent. of the selling price on all electrical energy generated, whether used for lighting or power, and the fact that the gas industry is to be burdened by a similar tax does not in any way justify this remarkable method of collecting revenue for the State. Although at times hard things may have been said in this country with regard to German competition in our electrical industry, there can be no electrical engineers who will not sympathise with the efforts made by their brethren in Germany to resist this imposition. It has been pointed out that the results of such a tax would be almost ruinous not only to the electricity supply industry, but to others. Firms generating their own electricity are to be taxed as well as supply companies and corporations, and in those cases where the cost of energy is an important factor in production, it is easily seen that the effect will be great. Thus it is predicted that, if the Bill is passed, a number of electrochemical manufacturers will be driven to move their works out of Germany, and a large iron-works which has an electric power station in connection with its blast furnaces estimates that the tax upon their output, including the tax of from 3·6d. to 6d. upon their electric lamps, will amount to no less than £2,670 per annum, or 1 per cent. of its share capital. The electric power industry has, in Germany as in this country, won its way largely by small savings in the costs per h.p.-hour, and in many cases the increased cost of 5 per cent. will prevent power-users from adopting electric driving in favour of steam or oil-driven plants. An increase of 5 per cent. in the cost of generation would, for instance, prevent a number of textile mills from adopting electric driving in place of steam driving, and there are numerous small works in which the same thing applies. Glow-lamps, it is proposed, should be taxed to the extent of 2·4d. for each lamp between 25 and 60 watts, 3·6d. from 60 to 100 watts, and 6d. above 100 watts; while gas mantles are to be let off with 1·2d. each, and a tax of 1s. per kg. is to be placed on arc-lamp carbons. The Government itself estimates that the revenue derived from the tax on electrical energy would be £870,000 a year, and on electric lamps and arc-lamp carbons £650,000. The creation of such a burden upon a growing industry upon which thousands depend for their livelihood would bring about disastrous consequences.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, DECEMBER 10TH.

Royal Society.

4.30 p.m. Meeting at Burlington House, Piccadilly, London. Among the Papers down for reading are the following: (1) "Electrolytes and Colloids; the Physical State of Gluten," by Prof. T. B. Wood and W. B. Hardy, F.R.S.; (2) "On the Specific Heats of Air and CO_2 at Atmospheric Pressure by the Continuous Electric Method at 20° and 100° C," by W. F. G. Swann; (3) "Potential Gradient in Glow Discharges from a Point to a Plane," by J. W. Bispham.

Mining Institute of Scotland.

6 p.m. Meeting at 92 Cadzow Street, Hamilton, N.B., when the discussion on the following Paper will be taken: "Experiments with Two Electrically-driven Pumps," by J. L. Galloway.

Institution of Electrical Engineers.

8 p.m. Meeting at 25 Great George Street, Westminster. Paper to be read: "Output and Economy Limits of Dynamo Electric Machinery," by J. C. Macfarlane and H. Burge. Time permitting, the following Paper will be read: "Commercial Electric Heating," by John Roberts.

FRIDAY, DECEMBER 11TH.

Northampton Institute Engineering Society.

5.45 p.m. Meeting at the Institute, St. John Street, Clerkenwell, London. Paper to be read: "Instrument Transformers," by R. E. Dickinson.

Physical Society.

7 p.m. to 10 p.m. Annual Exhibition of Electrical, Optical, and Other Physical Apparatus in the Physical Laboratory, Imperial College of Science, South Kensington.

SATURDAY, DECEMBER 12TH.

Institution of Electrical Engineers: Manchester Students' Section.

Visit to the Heysham-Morecambe single-phase railway of the Midland Railway Co.

Birmingham and District Electric Club.

7 p.m. Annual Meeting at the Colonnade Hotel, New Street, Birmingham, when the officers for the ensuing session will be elected.

TUESDAY, DECEMBER 15TH.

Finsbury Technical College Old Students' Association.

7 for 7.30 p.m. Third annual dinner at the Criterion Restaurant, Piccadilly Circus, London, Mr. P. V. McMahon in the Chair.

Institution of Electrical Engineers: Manchester Local Section.

7.30 p.m. Meeting at the University. Paper to be read: "The Electrical Discharge and the Manufacture of Nitrogen Compounds," by W. Cramp.

Faraday Society.

8 p.m. Meeting at the Institution of Electrical Engineers, 92 Victoria Street, London. Agenda: (1) "The Redetermination of the Electrolytic Potentials of Silver and Thallium," by F. J. Brislee; (2) "The Heats of Combustion of Aluminium, Calcium, and Magnesium," by F. E. Weston and H. R. Ellis; (3) "The Formation of Graphite by the Interaction of Magnesium Powder and Carbonates," by H. R. Ellis; (4) "Colloidal Barium Sulphate," by E. Feilmann.

WEDNESDAY, DECEMBER 16TH.

Institution of Electrical Engineers: Birmingham Local Section.

7.30 p.m. Meeting at the University. Paper to be read: "On the Use of Transformers as Choking Coils and Applications to the Testing of Alternators," by J. D. Coales. Mr. S. P. Smith will also reply to the discussion on his Paper, "The Testing of Alternators."

Junior Institution of Engineers.

7.30 p.m. Meeting at the Royal United Service Institution, Whitehall. Paper to be read: "Motor Omnibuses," by E. F. Boult.

Institution of Electrical Engineers: Students' Section.

7.45 p.m. Meeting at 92 Victoria Street, Westminster, London. Paper to be read: "Auto-transformers and Metallic Filament Lamps," by G. H. Stevens.

THURSDAY, DECEMBER 17TH.

Institution of Electrical Engineers.

8 p.m. Meeting at 25 Great George Street, Westminster, London. Paper to be read: "The Electric Discharge and the Production of Nitric Acid," by W. Cramp and B. Hoyle.

Rugby Engineering Society.

8 p.m. Ordinary meeting. Paper to be read: "The Utilisation of Exhaust Steam with Low-pressure Turbines," by E. Halliwell.

FRIDAY, DECEMBER 18TH.

Electro-harmonic Society.

8 p.m. Smoking Concert at Holborn Restaurant (King's Hall).

Institution of Engineers and Shipbuilders in Scotland.

8 p.m. Meeting at 39 Elmbank Crescent, Glasgow. Paper to be read: "Standardisation and its Relation to the Trade of the Country," by Sir John Wolfe-Barry, K.C.B., F.R.S.

Telegraph Traffic.—The Hanekin route was restored on the 3rd inst., and repair work on the line between Bagdad and Bassorah and *via* El Arich was also completed on the 1st inst. The submarine cable between Cotonon and Grand Bassam was again working on the 5th inst., after an interruption which occurred on October 28th last. Communication with Venezuela is interrupted, and the cables between Port Arthur and Chefoo, Pontianak, and Saigon and Dakar Conakry are all still down. Communication with Tauris has been interrupted since August 17th last.

A NEW MOUNTAIN RAILWAY IN TYROL

THE beautiful Province of Tyrol was one of the few parts of Austria which as lately as 1902 was without an electric railway. In the year 1903, however, a short mountain railway, partly on the cable system, was constructed up the Mendel pass; and this was followed by several short railways, such as the single-phase line in the Stubai valley. Subsequently, the Hungerburg and the Virgl mountain lines were opened, and finally, the Rittner line described in this article was opened last year. The Hungerburg and Virgl railways are both short electrically-driven cable railways; the former is worked with continuous current at 440 volts, and the latter with three-phase current at 3,000 volts. The Stubai single-phase line was opened in 1904; it is about 11 miles in length, and works with a line voltage of 2,500 volts. Six other railways are now being built, and when these are completed, the total length of electrically-equipped track in Tyrol will be 105 miles, including the tramways of Innsbruck and Meran. The railways under construction include four 750-volt continuous-current railways, and a local line between Innsbruck and Hall which is to operate at 1,000 volts continuous current.

The more interesting features of the Rittner line were recently described in *Elektrische Kraftbetriebe und Bahnen*. The line is situated to the north-east of the town of Bozen, between the valleys of the Eisak and Talfer, and runs up the side of the Rittnerberg, and along the plateau on top. This plateau is some 3,000 ft. above the level of the town of Bozen, and a magnificent panorama of the surrounding mountainous Dolomite district is obtained. The line which is single-track throughout, is nearly eight miles long, and about two and a half miles of this is constructed on the rack principle. A view of a portion of this section is shown in Fig. 1. Power is supplied to the trains in the form of continuous current at 750 volts, by means of a double overhead contact wire. In order to take advantage of the possibility of recovering energy when the trains descend the rack portion of the line, the motor-cars, which are equipped with the usual continuous-

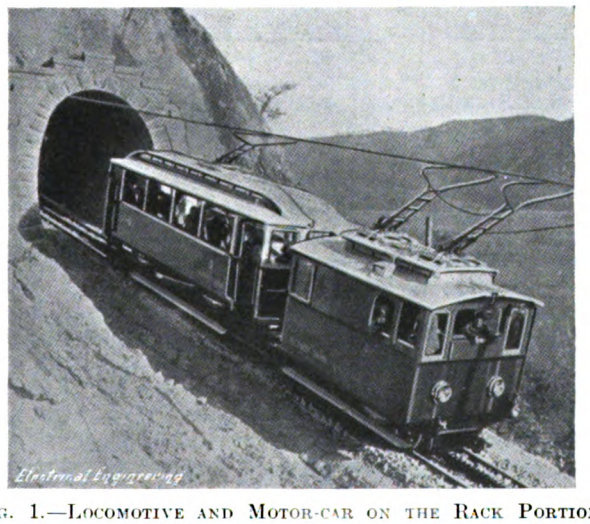

FIG. 1.—LOCOMOTIVE AND MOTOR-CAR ON THE RACK PORTION OF THE LINE.

current series traction motors, are taken up and down the rack by locomotives provided with shunt motors. When the locomotives descend the rack, the shunt motors act as generators and return energy to the line. On the level portions of the track, the motor-cars run by themselves.

Power for the railway is supplied from a water-power station in the Etsch valley, from which works the towns of Bozen and Meran are supplied with light and power. The sub-station for the railway is situated half-way along the rack portion about 22 miles from the works, and power is supplied in the form of three-phase alternating current at 46 cycles and 10,000 volts along an underground cable laid alongside the track. This cable not only supplies power for the railway, but also carries the supply for the towns of Bozen and Gries, and is in all over 30 miles long. The three-phase supply might have been applied direct to the working of the railway,

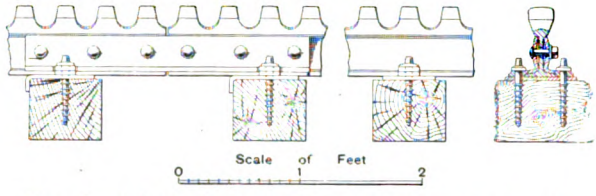

FIG. 2.—"STRUB" RACK RAIL, SHOWING METHOD OF ATTACHMENT TO SLEEPERS.

but a continuous-current system was chosen, partly on account of the necessity of two independent contact wires in the former case. As the energy is obtained from a water-power station, the losses incidental to the continuous current converting and distribution system were not of great importance; moreover, by the use of a buffer-battery, and regenerative working on the rack portion, the demand at the alternating-current side of the sub-station is kept comparatively steady during the day, and a better power-factor is obtained than would be possible with a direct three-phase system. Although regenerative working is possible with three-phase motors, the speed of descent depends on the frequency of the line, and for this reason in some of those rack railways in which three-phase motors are used, as, for example, the Jungfrau railway, the energy is not returned to the line, but is dissipated in water-cooled resistances. In the present case, by varying the excitation of the shunt motors, a useful regenerative effect can be obtained at any speed.

In the sub-station, the three-phase current is transformed down from 10,000 volts to 3,000 volts by means of a 300 k.v.a. transformer, and is then supplied at this pressure to the 325 h.p. motor of the converting set. This is a squirrel-cage induction motor, and was chosen in preference to a synchronous machine on the ground of simplicity. It is run up from the continuous-current side by means of the battery. The continuous-current machine, which is coupled to the motor with a flexible coupling, generates at 750 volts; and as the speed is comparatively high, namely 960 r.p.m., it is provided with commutating poles. A leather coupling, although it necessitates the use of four bearings, facilitates the removal of the generator armature and the substitution of a spare armature. The full-load efficiency of the set is given as 89 per cent., with a power factor of 0·92 and a slip of 1·2 per cent. As mentioned above, a battery is connected to the system to take the peaks in the load. This battery consists of 364 cells, and has a capacity of 296 ampere-hours on a one-hour rating, or 352 ampere-hours on a two-hour rating. A booster set is provided for charging the battery; the motor of this set is a three-phase induction motor, and is supplied from a transformer which also supplies the station lighting. To start this set, a low voltage obtained from a special tapping on the secondary of the transformer is impressed on the stator winding of the induction motor.

The track has some features of interest; the first portion, some half a mile in length, runs through the streets of Bozen, and is practically level, but in the next two and a half miles a difference in height of nearly 3,000 ft. is surmounted, the maximum gradient being just over 25 per cent. The remaining five miles

Digitized by Google

is practically level again, the maximum gradient being only 4·5 per cent. On the two-and-a-half mile steep portion, the track consists of Vignoles rails, weighing 45 lb. per yard, and the rack is on the Strub system, as shown in Fig. 2. The rack is laid in lengths of 13 ft., and the rails in lengths of 40 ft. Iron sleepers, which are usual on this class of railway, have in this case not been used, sleepers of larch being employed. The whole line is single track, and a turn-out is provided in the middle of the rack portion, notwithstanding the necessity for rack points entailed, as no suitable position for a turn-out could be found on the line. The trains each consist of a locomotive and a motor-car capable of carrying sixty passengers, and in the season these are run at intervals of one hour. There are never more than two trains on the rack portion at the same time. The contact wire is in duplicate, and is supported by means of a simple form of bow-spring suspension from wooden side poles. As the rails are used as a return circuit, the joints are bonded.

The rolling-stock comprises three rack locomotives, two of which are always in service, while the third is held in reserve; four motor-cars, three of which are generally in service; two passenger trailer cars; and four goods trailer cars. The locomotives, a longitudinal and transverse section of one of which is shown in Fig. 3, are each fitted with two 150 h.p. shunt-wound continuous-current motors, and can develop a continuous output of 300 h.p. at a speed of about four miles per hour, and a drawbar pull of some 27,500 lb. On account of the strain on the rack, and in order to improve the stability of the locomotive, two toothed driving wheels are used, each one being driven by a motor through double-reduction gearing with a total ratio of 14·73 to 1. The spur wheel axles are connected to the side wheel axles by connecting rods, and consequently the pitch diameter of the spur wheel must be exactly equal to the running diameter of the side wheels if no slipping is to occur. The tyres have been found to wear very little, however. As shown in Fig. 2, the rack rail is wedge-shape in section in the Strub system, in which a gripping device is provided to prevent all possibility of the pinion mounting the rack. This is shown on the extreme right of the longitudinal section of Fig. 3. An unusual feature in the arrangement is the interposition of a spring between the grip and the locomotive frame. The motors are not coupled direct to the spur-wheel gear, but drive through a coupling which is capable of slipping when the torque of the motor exceeds a certain amount. The use of such a slipping coupling is rendered necessary on account of the fact that if a motor were to short-circuit when the locomotive was descending the rack, the sudden braking effect would put too great a strain on the teeth of the spur wheels if the motors were rigidly fixed to the wheels. The locomotive is provided with two hand brakes, which work by means of four blocks on corrugated pulleys on each of the spur-wheel axles; the arrangement of the brake mechanism can be seen in Fig. 3. No brakes on the side wheels are required, since they are coupled to the spur-wheel axles. On each armature axle is an automatic brake which comes into action when a certain speed is exceeded, or can be worked by hand. So long as the contact wire is alive, the locomotive can be braked by regenerating also.

The electrical equipment of each locomotive comprises, as already mentioned, two shunt motors, with a continuous rating of 150 h.p. each. These motors, which weigh about 2·8 tons each, are four-pole machines fitted with commutating poles, and run at 750 r.p.m. The distribution of the load between the two motors is adjusted partly by altering the position of the brushes. Speed variation is obtained by means of a shunt resistance interlocked with the starting controller. The electrical equipment of each motor-car consists of two 45 h.p. series traction motors with the usual series-parallel control. The four-axle cars weigh 21 tons empty, and have a seating capacity of 58, and the locomotive weighs about 16·3 tons, so that the train-weight per seat amounts to 1,400 lb. The motor-cars have also pinions to engage with the rack, but these are merely for braking purposes, and are not motor-driven. The whole of the electrical equipment was supplied by the A.E.G. Union Elektrizitätsgesellschaft, of Vienna; the track was laid by a local firm; and the locomotives, with the exception of the electrical equipment, were supplied by the Schweizerische Lokomotivfabrik, of Winterthur.

REPORT OF THE COMMITTEE ON TRAMWAY BRAKES

Appointed by the Municipal Tramway Association

On page 647 of Electrical Engineering of November 12th, we gave an abstract of the Report of the Committee appointed by the Tramways and Light Railways Association to consider the subject of tramway brakes, as the outcome of certain suggestions by Colonel H. A. Yorke, contained in a Board of Trade report on the Highgate tramway accident of June, 1906. In response to these suggestions, a special committee was also formed by the Municipal Tramways Association to report on the subject independently. At the conference presided over by Colonel Yorke in October it was suggested by him that the two reports should be published together as one book, but on consideration, the arrangement was not found feasible. The report of the committee of the Municipal Tramways Association has now been issued, and, together with the illustrated descriptions of the various brakes investigated, fills a volume of about 100 pages.

The Committee consisted of the following members:

The then President, Mr. J. M. McElroy, General Manager, Manchester Corporation Tramways; the then Vice-President, Mr. J. Aldworth, General Manager, Nottingham Corporation Tramways; Mr. P. Fisher, General Manager, Dundee Corporation Tramways; Mr. J. B. Hamilton, General Manager, Leeds Corporation Tramways; Mr. H. Mozley, General Manager, Burnley Corporation Tramways; Mr. C. J. Spencer, General Manager, Bradford Corporation Tramways; Mr. A. R. Fearnley, General Manager, Sheffield Corporation Tramways (Hon. Secretary).

The report is prefaced by a number of extracts from Board of Trade reports on tramway accidents, and the Committee submit that the general conclusion to be deduced from this evidence is that the accidents, taken as a whole, have been due rather to the failure of the human element than to the failure of the brakes, and they think they are justified in going so far as to say that, with reasonable skill and care, the ordinary brake equipments which have been approved by the Board of Trade have, generally speaking, shown themselves equal to the work they have been called upon to perform. Taking all the tramway accidents which have called for local inquiry by the Board of Trade during the past six years, the Committee find that the fatalities in connection with such accidents, if compared with the total number of passengers carried, work out at one per 182,875,000. The Committee, however, fully realise that these accidents having taken place, a natural duty devolves on tramway operators to carefully consider means whereby the risk in future may be reduced, and, with this object in view, the Committee, in addition to considering the brake problem, have gone fully into the whole question of tramway accidents, with a view of indicating the directions in which improvements may be effected so as to secure greater safety to the travelling public. In considering the question, the Committee have given consideration to what they believe may be the causes which are likely to result or have resulted in runaway cars, and submit the following as embracing their views on the subject:—

The careless or thoughtless breaking or ignoring of important regulations. In dealing with this point, the Committee believe that the non-observance of regulations is the most common cause of all accidents on gradients, and it may be safely asserted that danger from this source will never be absolutely eliminated. Strict discipline, close inspection, and the framing of reasonable and sound regulations will undoubtedly reduce the risk to a minimum, and, in considering this point, the Committee are strongly of opinion that in all cases it is essential that power should be placed in the hands of some responsible person to see that such regulations, which are made from time to time for securing the safety of the public, are strictly enforced.

The growing tendency to construct and work tramways on very steep gradients and the running of cars on these gradients at too high a speed. The small margin of safety in working gradients of one in nine or steeper under ordinary street conditions is so important as to cause responsible persons to hesitate before recommending their construction. It is not too much to say that the safe operation of a gradient of one in nine or steeper depends absolutely on the surface of the rails being kept clean and free from grease; also on the fixing of low maximum speeds for gradients of this character, and careful supervision to ensure that these speeds are never exceeded.

The employment of men who are not from various causes fit for their positions, and the insufficient amount of training and testing of men in charge of cars. Experience has shown that the best tramcar drivers are taken from certain types and classes of men. On practically all systems, drivers are selected from employees in the Tramways Department, whose experience, either on the rear of a car as a conductor, or as a depôt employee, is such as to fit them for the position of driver. No man ought to be appointed a driver of an electric tramcar who has not first passed a careful medical examination. A rigid and careful examination as to fitness in handling a car should be made by a responsible officer, after the man has been thoroughly trained in his duties. The supervision of the training of drivers should, where practicable, be done by one man, in order to secure uniformity. Periodical testing (medical and practical) of men is a necessity of safety.

The danger of adopting new forms of brakes without the fullest knowledge as to their action under all conceivable conditions of service. The greatest care should be exercised by tramway operators in adopting any new form of brake without adequate trial and experience. Theoretical considerations alone are not sufficient for the purpose of determining the efficiency or otherwise of any new form of brake.

The disregard of the absolute necessity of constant and careful inspection in the depôts of all brakes and equipments generally and the danger of allowing cars which have exhibited defects to remain in service on the road when they should have been sent to the depôt.

The running of cars on long gradients without suitable track brakes. The Regulations of the Board of Trade require that on tramway systems with gradients of 1 in 15 or less track brakes should be fitted on all cars. There are, however, conditions due to curves, traffic, &c., which necessitate the adoption of track brakes on long gradients of less than 1 in 15.

Drivers of cars losing conscious control of their actions under trying and critical conditions. The Committee believe that danger from this cause will always, to some extent, exist. The cause of panic on the part of a car driver, in practically every case, is due to the occurrence of some unusual phenomenon in connection with the working of the controlling apparatus under his charge, and panic having once taken possession of a man, it is impossible to say what his actions will be. It is more than probable that they will be of a sub-conscious and automatic character, formed as a habit resulting from experience in the operation of his brakes. Assume, for example, that a man is in the habit of retarding the speed of his car by means of the ordinary hand brake, and that, in his experience, he has not had to deal with a very greasy rail. He may have been fully instructed, but one day suddenly finds that the brake does not have the usual retarding effect when applied in the ordinary way. Instinctively he applies the brake harder, with the result that he skids the car wheels. He may or may not remember that his trainer told him that under such circumstances it is necessary to release the brakes, open the sand valves, and reapply the brakes, or he may remember his training when it is too late. To reduce this risk involves the designing of a brake where the minimum of skill on the part of the driver is required, and is of such constructional design as to win the absolute confidence of the man whose duty it is to operate it.

The Committee consider that this train of thought suggests that a necessary quality in an ideal brake is that its application to the fullest possible extent does not involve its failure under any circumstances, obviously meaning that the danger resulting from skidding wheels shall not exist. Simplification of braking apparatus is desirable. All brakes, however, no matter how simple, are subject to failure of some description. Two alternative methods have been suggested for reducing the risks to a minimum, namely:

(1) To have more than one brake per vehicle each quite independent in action, so that in the event of failure of one, the other brake or brakes could be called into use; and (2) To

Digitized by Google

have only one brake per vehicle, but so designed that in the event of failure in the ordinary method of application the brake would be automatically applied and not released.

The first method is the one which has been generally adopted, but the second method, if realisable in the fullest degree, seems desirable, and the Committee suggest that an ideal brake equipment would be one where the same gear is used for all purposes, viz., service, emergency, and coasting, and worked from a single lever by the driver; the only difference between easy service stops and quick emergency stops would be one of degree of application, and that in the event of failure or accident, the result would be the application of the brake and not its release. An ideal brake would also be one that could be operated at any time by the conductor of the car, and be equally effective whether the car was running forward or backward. It should, as far as possible, be independent of auxiliaries (sand, &c.).

It has often been stated, and generally agreed, that, inasmuch as the conditions on different systems vary, a universal type or system of brakes is not only impossible, but undesirable, and that whilst a certain type of brake may be excellent for one system, it is not necessarily good for another where the conditions are different. The Committee, however, are not prepared to admit the correctness of this view. Not many systems are so flat that they have not a gradient sufficiently steep to require special apparatus and precautions. On the other hand, all systems require quick-acting brakes to avoid street collisions with other vehicles. This being so, the Committee suggest that tramway conditions are, speaking generally, of a standard character, and are, therefore, open to standard treatment.

The following types of brake equipment have been generally adopted in this country, in accordance with the requirements of the Board of Trade, viz.:—

Wheel Brakes.—In this report the term "wheel brake" is used to mean any form of brake where the sole retarding effort is obtained by means of the application of blocks to the periphery of the car wheels. The most common arrangement is one in which the driver applies cast-iron blocks to the periphery of the wheels by means of a crank handle fixed on the car platform operating through various levers in order that the blocks may be applied with sufficient pressure. The design of this brake is practically standard. Apart from the difficulty inseparable from the principle of action, viz., the skidding wheel, it has proved an excellent piece of apparatus. The crank handle, combined with the ratchet, is a convenient and handy arrangement for the driver. The winding-up of a chain on the brake spindle, though somewhat severely criticised by Colonel Yorke, has not given much trouble in practice. Many improvements have been put on the market, and largely adopted, to facilitate the taking up of slack and the reduction of chain link wear and friction, without materially departing from the principle of winding a chain on a barrel. The Committee are unable to agree with the remarks of Colonel Yorke, in his report on the Highgate accident, relative to the question of the proper position of brake blocks on the wheels; nor are they able to agree with his observations as to the requisite amount of clearance between the blocks and the wheels, and the necessity of grinding or surfacing brake blocks in a special machine before being used. The arrangement of levers and the design of the same on most modern wheel brakes are thoroughly mechanical, and properly proportioned for the work they have to perform. Care should always be taken that adequate leverage is provided.

Electric Brakes used for Emergency Purposes.—In these brakes the regenerative action of the motors is utilised for effecting emergency stops. The objection to this type of brake is that at times of emergency the car driver, accustomed as he is to use his wheel brake for ordinary service stops, involuntarily tends to put on such brake harder; he thus locks the wheels and renders inoperative the rheostatic brake.

Track or Slipper Brakes.—On tramway systems with gradients of 1 in 15 or less the cars are, by the Board of Trade Regulations, required to be equipped with track or slipper brakes.

Mechanical Track Brakes.—The type of mechanical track brake in general use consists of two or more hard wood or cast-iron shoes, pressed against the surface of the track by means of suitable lever arrangement, worked primarily from a wheel or lever on the platform of the car. The mode of operation is generally to apply this auxiliary brake when descending steep gradients sufficiently hard to supply the necessary retarding force to balance the gravity forces. If it is required to stop the car, only a light application of the wheel brake is necessary in addition. This form of brake has proved very effective in the operation of tramways on steep gradients; it is approaching the ideal brake on account of the fact that it is not liable to failure when applied to its maximum extent, also to its non-liability to get out of order. It is simple in construction, and requires practically no skill in application. Notwithstanding the transference of weight from wheels to track shoes, its effect is to materially lessen the tendency of the skidding wheel, on account of the cleaning action of the shoe on the rail. An advantage in this type of brake is gained by multiplying the points of application, thus utilising the weight of the car at four points instead of two. As a result of experience and tests with this type of slipper brake, it has been found that on a greasy rail cast-iron blocks are more effective than wood blocks, whilst on a dry rail wood blocks are more effective than cast-iron blocks. Its main disadvantages are that it is slow in application, and its effectiveness is limited to the available weight of the car.

Magnetic Track Brakes.—A development and improvement of the rheostatic brake is the connection therewith of magnetisable metal shoes hung between the car wheels, the magnetising coils of which are in series with the car motors, and rheostat when the motors are used as generators for braking purposes. These metal brake shoes are so arranged that when magnetised they are attracted to the rails, and thus assist in the retardation of the car by the beneficial effect of the friction set up, which is directly proportional to the degree of magnetisation of the track brake shoes. Theoretically the utilisation of a magnetic brake shoe properly designed and proportioned should be excellent both for service and emergency braking; its operation is of necessity economical when compared with other forms of power brakes, as it utilises the waste energy primarily obtained from the momentum of the moving car. Further, owing to its magnetic properties, its effectiveness is not limited to the weight of the car. When the car is travelling at a speed in excess of four or five miles per hour, it is practically instantaneous in its action. Disadvantages of purely magnetic brakes are unfortunately serious. They are not simple brakes, their operation depending upon the correct working of a number of the more delicate portions of the car equipment, and are consequently liable to derangement at inopportune times. It is impossible for the driver to tell whether the brake is available for action or not until his car is under way. A serious disability in one of the earlier and well-known forms was the tendency to produce skidding when over-applied.

Combined Mechanical and Magnetic Track Brakes.—Recent developments have been in the direction of combining the best features of both the mechanical and magnetic track brakes. In some cases this has taken the form of simply fitting to the ordinary magnetic arrangement a system of levers for applying mechanical pressure to the upper portion of the track shoes. In others an ordinary mechanical track brake is supplemented by a magnetic shoe capable of moving in the track line relatively to the car frame. When this auxiliary shoe becomes magnetised its attraction to the track is utilised to produce a dragging movement which, by a system of levers, increases the downward pressure on the mechanical shoes. For coasting purposes these brakes can be applied mechanically while the car is at a standstill, before commencing the descent of a gradient, and the speed may be regulated by gradually increasing the pressure of the blocks mechanically or by magnetism. Either form of application is sufficient to control the car without the assistance of the wheel brake, thus eliminating the danger of the skidding wheel or the uncertainty of the magnetic brake acting through failure of the electrical equipment. In some cases an arrangement is provided whereby the magnetising coils of the brake shoes may be excited by utilising the line current, but in the event of the line becoming dead, or the trolley leaving the wire at a critical moment, this device would be useless.

Power for Brake Application.—The speed of application and manipulation of any brake is necessarily vital to its effectiveness. In manually operated brakes much improvement is possible in this direction, and any device that has for its object the quick taking-up of slack, and hence the quick application of the brake blocks or track shoes, would be an important improvement. This desirable result may be accomplished by the use of power for the application of the brakes. The most common form of power used for this purpose is compressed air, and the Committee are impressed with its effectiveness where they have seen it in use, although, in common with other forms of power brakes, it is more complex than a purely mechanical brake. In the United States and the Continent, air brakes are almost universally used, but so are trailer cars, and the use of these trailer cars almost compels the adoption of an air or similar brake equipment. The problem for unit vehicle control is not quite the same, as it is conceivable that manually operated brakes may be improved to achieve the results already accomplished by the power applied brakes, that is, so far as quick application and manipulation are concerned.

Run-back Preventers.—One of the most likely things to cause a car driver to be seized with panic is when, through current

Digitized by Google

failure or other cause, his car begins to run back down a grade, and the Committee are of opinion that cars operating on gradients should be equipped with run-back preventers which should act automatically.

SUMMARY AND CONCLUSIONS.

At the root of the brake problem and the problem of the prevention of tramway accidents generally, two factors stand out prominently, and continually force themselves to the front for consideration, no matter from what standpoint the subject is approached. These are :—(1) The weakness of the human element—that ultimate element necessary for the safe operation of cars—no matter how perfect the brakes may be. (2) The greasy rail, and the consequent danger of the skidding wheel.

The Committee think they are justified in saying that the human element has been the chief cause of most serious tramway accidents, and they trust that the fullest consideration will be given by tramway authorities and the Board of Trade to the suggestion contained in this report as to the selection, training, and control of tramway employees and staff. Improvements in tramcar brakes should be largely in the direction of reducing the importance of the human element, and should follow the lines set forth by the Committee in their suggestions as to ideal braking apparatus. Control of cars by purely mechanical means without sand, &c., is possible on steep gradients at reasonable speeds on practically clean rails, but with greasy rails, such as are common in all towns, proper control is impossible without the use of (*a*) sand, &c., for increasing the adhesion, or (*b*) magnetism for increasing the downward pressure on the rails in excess of the weight of the car. The Committee feel that the safety of passengers when descending steep gradients should not depend on the safe working of a sand box and gear, and magnetic arrangements alone are as yet not sufficiently reliable to be entirely depended upon.

The brake problem therefore resolves itself largely into a question of track cleaning—the keeping of the rails free from greasy matter.

The remarkable effectiveness of track brake shoes for cleaning purposes makes that system the most reliable to adopt for safely negotiating steep gradients. The Committee find that serrated cast-iron shoes are better than smooth cast-iron, and, taking the average of track conditions—wet, dry, and greasy—cast-iron is better than wood. It will be noted on the test sheets appended to the report that on dry rails the friction coefficient of cast-iron is much lower than that of wood, therefore increased leverage may be required in the case of iron. The maximum pressure possible on track shoes without danger of derailment depends very much on the type of the track brake. With flanged blocks and with the weight of the car taken on a steady base, the downward pressure could be safely brought to a high percentage of the total weight of the car, but with track brakes where the weight is taken midway between the axles, the maximum downward pressure should not exceed 40 per cent. of the total weight of the car unloaded.

The danger of the skidding wheel, and its consequent rendering inoperative of the ordinary wheel and rheostatic brakes and the magnetic track brakes, led the Committee to consider as to whether or not it would be desirable to dispense altogether with wheel brakes, but after further deliberation they cannot recommend this course. Wheel brakes are, under clean rail conditions, most effective. They are not the only brakes which may cause skidding. The rheostatic alone, or the rheostatic in combination with the magnetic track brake may cause skidding if the coefficient of static friction between wheels and rails is low on account of the greasy state of the rails.

The practical result of the Committee's deliberations and investigations is that a brake which can be applied instantaneously either by hand or power from a single lever to both rails and wheels, is desirable, and so designed that the track shoes take the full allowed percentage of the car weight before the wheel brake comes into operation. Having regard to the average tramway conditions, this arrangement is most likely to best fulfil general requirements. Tests and experience under service conditions will show what percentage of the total weight of the car may be efficiently transferred to the track shoes, and in this connection it must be remembered that one of the most important effects of such shoes is to clean the metals. A brake of this description will practically obviate the necessity of the use of sand for braking purposes, and this is most desirable.

The Committee are quite in accord with the views expressed by Colonel Yorke as to the undesirability of an independent brake for purely emergency purposes. To avoid the danger of cars running back on gradients through failure of current, or otherwise, it is desirable that they should be fitted with automatic run-back preventers. So long as sanding apparatus is necessary for braking cars, attention should be paid to the design of the hopper and operating gear. The hopper should be of ample capacity. The gear should be of good mechanical design, and so arranged that both rails are sanded simultaneously, and that the driver should be able to apply sand at the rear end from his platform in the event of the car running backwards. The Committee are also in accord with Colonel Yorke as to the advantage, for braking purposes, of steel tyres as against chilled iron.

The report is followed by full descriptions of a number of patterns of brake and results of actual tests.

CORRESPONDENCE

COAL CONSUMING COMPANIES AND THE MINERS' EIGHT HOURS' BILL.

To the Editor of Electrical Engineering.

Sir,—During the last week many gentlemen who, for the most part, control limited companies which would suffer severely if this Bill became law, have written to me for advice as to the appropriate way in which a protest should be made by their companies to the House of Lords.

I have, consequently, prepared some suggestions for resolutions to be forwarded to the Upper House, and I shall be glad to send them to any of your readers who would like to make use of them, on hearing from them at this address.

As this Bill is likely to engage the consideration of the Lords at an early date, no time should be lost in moving. I am informed that protest resolutions of this character from business men will receive weighty consideration.

Yours faithfully,

G. E. Raine.

(*Organising Secretary, Coal Consumers' Defence League.*)

Sanctuary House, Tothill Street, Westminster, S.W.

December 2nd, 1908.

STORAGE BATTERIES FOR THE IMPROVEMENT OF LOAD FACTOR.

To the Editor of Electrical Engineering.

Sir,—In Mr. Lackie's most interesting and valuable inaugural address, he is reported to have said that the "good" storage battery has not arrived as yet. Now, sir, though we are all pining for the "ideal" storage battery, yet surely that need not debar us from using the batteries that are on the market if there is anything to be gained thereby. Mr. Lackie speaks of the figure of £80 per kilowatt of maximum demand, of which, no doubt, his steam plant and transmission and conversion plant (to his city sub-stations) would account for some £40 to £50. Is he aware that a battery big enough to take 7,000 kw. off the top of his peak could be got for some £5 per kilowatt (ex. auxiliaries)? No doubt he will reply that I have forgotten the fogs. In reply to that, I would say that a battery for a continuous five-hour discharge could be got for some £10, which would leave three and a half hours of additional peak available to deal with fogs.

If Mr. Lackie can show that his worst fog load adds an area above the 14,000-kw. line of his published diagram, integrating more than 24,500-kw. hours (7,000 × 3·5), I will then admit that Glasgow is an unfortunate (though not impossible) city in which to use batteries for lighting. But in that case I would still contend that it would pay him to put them in for power. Assuming, for example, that his summer curve, as published, is practically all "power," the above £10 battery would take up 2,500 kw. off his engine and boilers, and enable the standby losses of boilers corresponding with this output to be saved by shutting down boilers to this extent for the whole year. Mr. Lackie himself supplies the data for arriving at the annual coal saving, which is roughly 400 tons per boiler shut down. He would really be able to shut down some additional boilers above those needed for the 2,500 kw., because he would have at all times of the summer a battery standby equal to a one-hour discharge at some 7,000 kw. during the first hour of the fog, when boilers could be started up if thought desirable. So that really it might be possible to shut down boilers and engines all the year round (or nearly all) to the extent of something like 5,000 kw., with corresponding saving in coal, wages, and repairs.

The fog might last for the whole 12 hours of the day, but this would not affect the batteries, as the motor load taken up by them only integrates up to some five hours, and the remainder of the evening peak would be carried in the usual way with the steam plant. If some 10 per cent. (including interest, sinking fund, maintenance, and depreciation) on the capital cost of steam plant, and some 17½ per cent. on that of accumulator plant, are the relative annual expenses, exclusive of all savings on fixed charges introduced by the cells, and if the capital costs are in the ratio of 3 to 1 or 4 to 1, surely there is a case

Digitized by Google

for accumulators, even in their present stage of development. But, as a matter of fact, it can be shown that the savings in fixed charges will alone much more than pay for the perpetual maintenance of the cells, so that the only question outstanding is not the existence of, but the amount of, the saving in interest on capital.

Yours faithfully,
A. M. Taylor.

INQUIRY.

Glass Boxes for Accumulators.

To the Editor of Electrical Engineering.

Sir,—Could you put us into communication with any firm who manufacture glass boxes for storage batteries? Thanking you in anticipation of your kind reply.

Yours faithfully,
The Ronald Manufacturing Co.

Milner Works, Barnsbury Street, N.

BOOK REVIEWED

High-Speed Dynamo Electric Machinery. By Messrs. H. M. Hobart and A. G. Ellis. 497 pp. 9¼ ins. by 6 ins. 355 illustrations. (London: Chapman and Hall.) 25s.

This volume continues the series which Mr. Hobart has been engaged on for some years, dealing with electric generators and motors from the designer's and constructor's point of view. The importance of the subject of high-speed machines has rapidly developed, and, apart from such isolated Papers and descriptions as have been published in the technical Press, there has been no really comprehensive book of reference until the appearance of the one under review. The authors have been fortunate in obtaining the assistance of over a dozen firms, all well known as manufacturers of turbine sets, and the foundation of the book-data, drawings, and photographs appears to be as nearly up to date as it is possible to expect.

The first 64 pages are devoted to general considerations and design coefficients, with a chapter on materials suitable for use in the construction of high-speed machines. The figures and curves in this section are stated to be "rough but fairly representative values" for normal designs, and are interesting as indicating the authors' ideas based on the analysis of such designs as they have confidence in. On pages 46, 48, and 51 there are given three most instructive sets of curves, showing the influence of low-loss core material on the cost and heating of high-speed machines. Presumably these curves are calculated on the sheet-maker's guarantees and not on core-loss tests of actual machines, which would include losses due to building the core.

Perhaps the most important section of the work is that devoted to alternating-current generators (254 pages), in keeping with the authors' frequently expressed view that turbine speeds are more suitable for alternating- than for continuous-current generators. About 65 pages are usefully devoted to the broad considerations of design before studying the best form for the detailed designs of different sizes with their possible speeds and frequencies. The preliminary chapters deal exhaustively with the pressure regulation and with the influence of output and speed on size. The table on page 100, giving leading particulars of thirty alternators by well-known makers, with outputs of from 80 to 7,500 k.v.a., is of great interest, and would have even greater interest if the dates of manufacture had been given. Chapters VIII., IX., and X. deal respectively with the authors' designs of 400, 3,000, and 6,000 k.v.a. alternators at different speeds. The strong condemnation of two-pole designs will no doubt be accepted by most designers as more than a mere expression of opinion.

The question of excitation voltage for revolving field alternators is not dealt with specially, although it is an important one for large machines, where it is difficult to devise a satisfactory winding of such cross-section that the exciter and rotor slip-rings are of reasonable dimensions. The remaining chapters in the A.C. section deal with the construction of stators and rotors, and a few examples of existing machines are given in more or less detail. The concluding chapter analyses the stresses in the rotor.

Throughout the section on continuous-current generators the authors emphasise the fact that continuous-current machinery is not suited to turbine speeds, a fact recognised by most designers at present. It will be very interesting to read this section after a few years have elapsed, when the survival or extinction of this class of machine has determined itself. The principles of design seem to be so well understood that it would appear that nothing short of a miraculous development of special commutator brushes could make large D.C. turbo-generators successful, although something might be expected from reduced turbine speeds. As in the preceding sections, the broad considerations of design are dealt with first in a very clear and simple manner. A very large amount of work has been done by the authors in providing curves from which the preliminary dimensions of any machine may be seen at a glance. These tentative designs are not intended to be worked to, but form a valuable time-saving factor in putting the designer in possession of a mass of information in an easily digested form. Several excellent modern examples of continuous-current turbo-generators are illustrated and described, and a few pages are devoted to describing homopolar machines, which have reached a commercial stage in America. The stresses in revolving armatures are dealt with, and the important question of brushes and brush-holders is fully considered, without, however, any very definite expression of opinion as to the best type, metal, carbon, or compound.

It is impossible to review this book without a feeling of profound respect for the immense amount of personal work put into it by the authors, whose previous work entitles their opinions to the most careful consideration. The style of production of the book is uniform with the preceding volumes, but there are a good many obvious misprints. A table giving references to leading patents would have been well worth the space occupied.

A New Electric Railway in the Alps.—The construction of a new and important electric railway in the Alps has been commenced. According to *Elektrotechnik und Machinenbau*, the railway is to run from the Grisons district *viâ* the Poschiavo pass and Tirano, through Edolo to Brescia. The section Edolo Brescia is nearing completion, but the concession for the construction of the section Edolo-Tirano has not yet been granted.

London (Westminster and Kensington) Electric Supply Bill.—The Parliamentary Committee of the London County Council, in a report upon this Bill, state that the various protective provisions as to street works, &c., desired by the Council were agreed with the promoters so far as such provisions had been inserted in the London Electric Supply Bill, and Sir Luke White's Committee were urged by counsel for the Council to insert provisions which they had refused in the case of that Bill giving the Council the right to be heard on the question of the route of electric lines, and the same rights as a local authority under section 14 of the schedule to the Electric Lighting (Clauses) Act, 1899. The Councils of the City of Westminster and the Borough of St. Marylebone objected, and the Committee adhered to their decision in the case of the other Bill. The Committee think the Council should endeavour, as in the case of the London Electric Supply Bill, to obtain the amendments refused by the Select Committee as to the route of electric lines and as to powers for the Council under section 14 of the schedule to the Electric Lighting (Clauses) Act, 1899, and they recommend that all necessary steps be taken to secure the insertion in the Bill of the usual powers for the Council with regard to street works and the protection of the Council's property.

TRANSFORMERS

Some Practical and Theoretical Considerations

Comparisons of Different Types.—The Paper on transformers by Messrs. A. P. M. Fleming and K. M. Faye-Hansen, of the British Westinghouse Co., on Tuesday of last week, before the Manchester Local Section of the Institution of Electrical Engineers, commenced with a general comparison of the rectangular and circular shell and core types indicated in Fig. 1. It was mentioned that for single-phase transformers alone the following types were used on a large scale :—Shell type with rectangular coils, as built by the Westinghouse Companies, the Siemens-Schuckert Works, &c. Circular shell type, as built by the British Electric Transformer Co. Core type, with rectangular and with round coils, as built by the Westinghouse Companies, the Allgemeine Electricitäts Gesellschaft, Johnson Phillips, and other firms.

Typical designs had been worked out for each type, and some figures were given as a comparison in the case of a 100-k.v.a 50-cycle transformer on the basis of iron-weight plus copper weight multiplied by three as giving a figure approximately proportional to the cost of actual material. From the figures given it was seen that the difference in the amount of material for the four types was very small. The rectangular shell type is in all cases (especially for high copper space factors) slightly superior to the other types, while the circular shell type for low copper space factors (*i.e.*, for high voltages) is somewhat inferior to the other types.

The Paper then passed on to comparisons on the basis of electrical performance, and iron and copper losses were worked out for all four types, both as power transformers with their maximum efficiency at full load and as lighting transformers with their maximum efficiency at two-thirds of full load. From the tables given, however, it was seen that the difference in electrical performance between the types is too small to be of importance in practice, though the difference in losses for the types is of the same order as the difference in the cost of the active material. All types are equally adaptable as power and lighting transformers.

In these comparisons all the most important electrical qualities of the transformers were taken into account, except the reactance, which together with the copper loss determines the regulation of the transformer at different power factors. This feature was accordingly considered for various concentric and interleaved arrangements of the windings, and it was finally shown that with suitably designed windings *any* regulation can be obtained with any of the above types. For the shell types it will generally not be advisable to use the single concentric winding, as the regulation at low power factors will be too bad. The double concentric winding, however, gives fairly good results, but for practical reasons this arrangement of winding is very seldom used for the rectangular shell type. For the core type the single concentric winding gives fair regulation, and the triple concentric winding very good regulation. If the interleaved winding is adopted, the core type requires a larger number of coils than the shell types for obtaining the same regulation. The possibility of obtaining any reactance for any type of transformer is also of interest from the point of view of banking of transformers of different types, for it is evident from the figures given by the authors that it is possible in any type of transformer to arrange the winding so that it will parallel with any given transformer of the same or of other type when the data regarding ratio, connections, and impedance voltage for the existing transformer are known. This is made much easier because it is possible for any given transformer and winding arrangement to alter the reactance by altering the ratio of copper to iron loss.

The important question of the relative cooling surfaces available with the different types was next gone into. From the figures given for the same typical set of transformers it was seen that as regards the cooling of the copper the core types in this respect are better than the shell types. Especially is this so in the case of the circular core type, as the surface copper to iron and iron to copper for this type of transformer to a large extent can be considered as active cooling surface without diminishing the space factors. The cooling of the copper of the rectangular core type, and still more of the rectangular shell type, can be greatly improved when the sandwich winding is adopted by spreading the coils—*i.e.*, by bending them outwards outside the iron. This increases the surface considerably without reducing the space factor, and is standard practice for Westinghouse transformers of these types. The circular shell type is, as regards the cooling of the copper, inferior to any of the others, but as regards the cooling of the iron, superior even to the rectangular shell type, as theoretically each punching has cooling ducts on both sides.

In investigating whether the assumption made in the above considerations of approximately the same copper space factor for the different types was justified figures were gone into which showed that except for the double concentric winding, where the core types will give smaller copper space factors than the others, the different types in this respect are approximately equal.

Influence of Steel Alloys of Good Magnetic Quality.—A given frame has for given space factors, &c. (*i.e.* given voltages) the same maximum efficiency, whatever its rating. If, therefore, for special reasons it is desired to obtain for a 50-k.v.a. transformer the same standard efficiencies as for the 100-k.v.a. size,

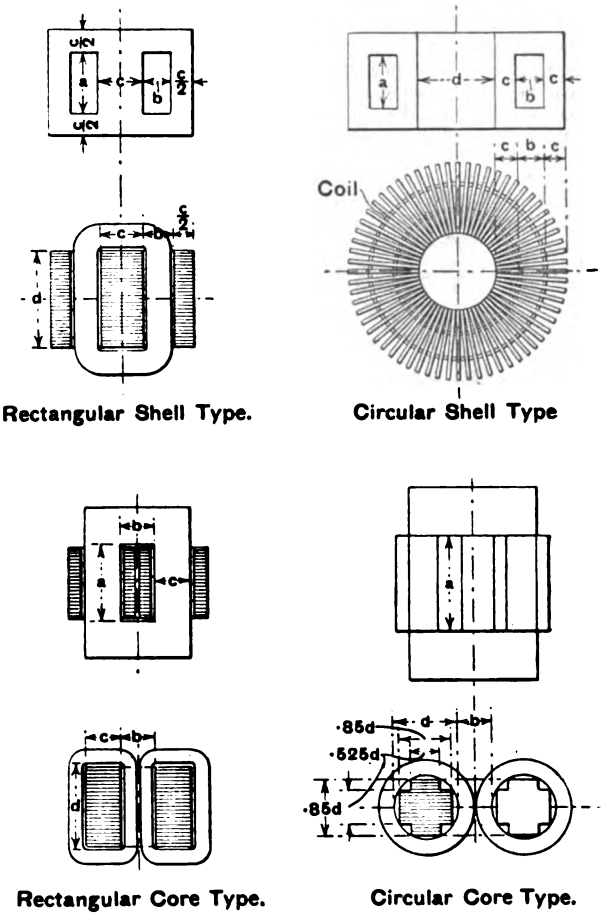

Fig. 1.—Transformer Types.

the same amount of active material will be required as for a standard 100-k.v.a. transformer. It is further seen that the demand for abnormally high efficiencies compels the manufacturers to try to use excessively high space factors, so that the insulation is cut fine and the reliability of the transformer reduced. The metallurgist has, however, assisted the manufacturer in this matter by offering alloyed iron having considerably better magnetic qualities than the material previously obtainable. If, for instance, a special alloyed iron having approximately 60 per cent. losses at the same induction and periodicity compared with ordinary iron is employed, then the same maximum efficiency can be obtained at 0·465 of the original weight. If the same efficiency is required at the same output as with ordinary iron, the product of induction and current density can be approximately 2·75 times larger than before.

The most economical ratio of copper and iron losses.—In many hand-books, &c., it is stated that the ideal condition is to obtain the maximum all-day efficiency. This, however, continue the authors, is not correct, as it is based on the assumption that the price per unit is constant, independent of the load of the generating station. It must, however, be taken into account that the iron loss goes on always, and therefore corresponds to 100 per cent. load factor, while the copper loss

Digitized by Google

has its maximum when the load is maximum, *i.e.*, the copper loss increases the peak load, so that the unit of copper loss will cost considerably more than the unit of iron loss. To

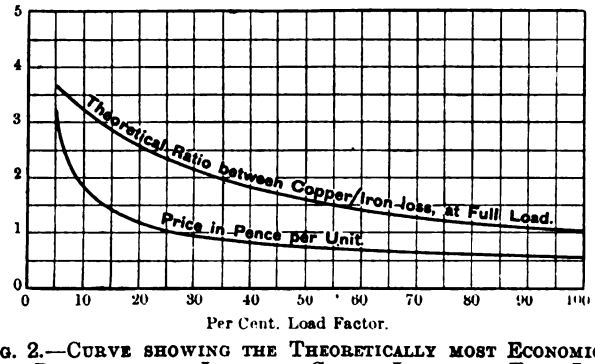

FIG. 2.—CURVE SHOWING THE THEORETICALLY MOST ECONOMICAL RATIO BETWEEN IRON AND COPPER LOSSES AT FULL LOAD FOR GIVEN LOAD FACTOR AND PRICE PER UNIT.

treat the subject mathematically in a simple manner, the authors assume that the load per day consists of full load for a time of $24 \times a$ hours, corresponding to the load factor a (the rest of the time no load at all), and that the price per unit b_a alters with the load a as per curve Fig. 2.

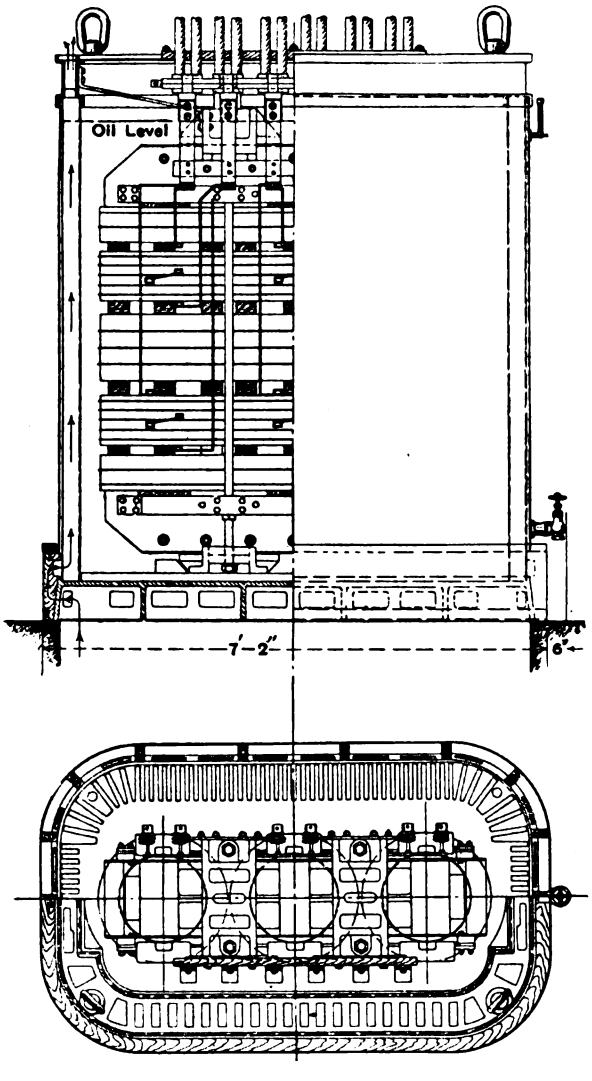
The values are given in the curve in Fig. 2.

It would, however, be good practice to make the ratio between copper loss and iron loss still smaller than according to this curve for the following reasons:—(1) The iron loss increases somewhat more slowly than proportional to the square of the induction. (2) The larger the ratio between copper and iron loss the smaller will be the wire used, whereby the copper space factor will be reduced and the losses and the price accordingly increased. (3) The smaller wire and the larger number of turns means a more expensive transformer. (4) A high copper loss means bad regulation, which will have to be compensated for by the use of cable of larger dimensions, &c.

The authors therefore recommend that for ordinary voltages the ratio between copper and iron loss at full load should not be larger than about 80 per cent. of the values given in the curve. For transformers for very high voltages and comparatively small outputs the ratio between copper and iron loss should be considerably lower.

Comparison of Methods of Cooling.—The most important practical difference between types of transformers is the method of cooling. Efficient cooling is, of course, essential to minimise the fire risk, to prevent deterioration of the insulation, ageing of the iron, and increase in copper loss.

The different methods of cooling in actual service are:—Natural draft; oil insulated self-cooling (O.I.S.C.); air blast: oil insulated air blast (see Fig. 3); and oil insulated water-cooled with cooling either internal or external.



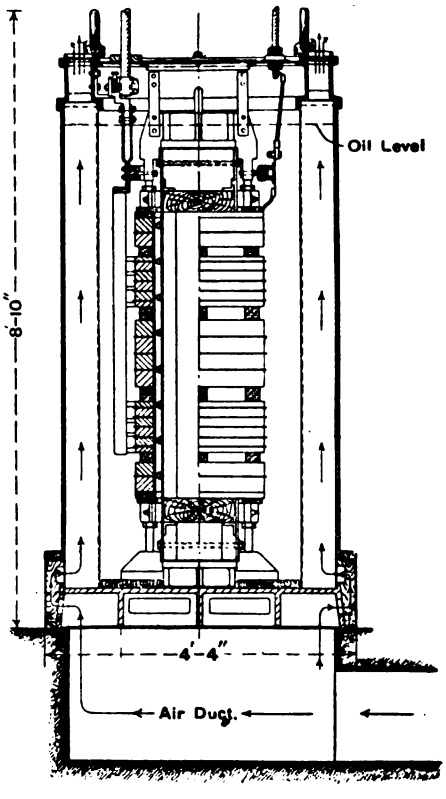


FIG. 3.—THREE-PHASE OIL-INSULATED AIR-BLAST CIRCULAR CORE TYPE TRANSFORMER FOR 1,700 K.V.A. 5,000 VOLTS, 25 CYCLES.

The iron loss is X per cent. of the full-load output of the transformer. The copper loss at full load is Y per cent. of the full output. According to a previous assumption the product of $X \times Y$ will be constant for a transformer of a given size and price.

The price for the losses $(X \times 24 \times b_{(a=1)} + Y \times 24 \times a \times b_a)$, should be a minimum. From this it follows that the most economical ratio between copper loss and iron loss is—

$$\frac{X}{Y} = \frac{b_{(a=1)}}{a \times b_a}.$$

The first two types possess the advantage of being entirely self-cooling, and do not require any auxiliary apparatus such as blowers or pumps, but practically the limits in output for which the natural draft type can be economically built are very narrow, since as the size of the transformer increases, the exposed surface per unit volume of active material decreases rapidly. The O.I.S.C. type can be built for very much greater capacities than the natural draft type, since the heat conduction between metal and oil is very much greater than between metal and air, but the natural draft type has the advantage of greater cleanliness,

Digitized by Google

especially in case of repairs or alterations and ease of transport. On the other hand, in the O.I.S.C. type there is a greater uniformity of temperature throughout the active material, and the thermal capacity is increased, so that overloads can be carried for longer periods. Further, the O.I.S.C. type is capable of withstanding a higher temperature without injury than the natural draft type, due to the fact that the organic insulating materials being oil immersed do not deteriorate so rapidly. The scope of the natural draft transformer is also restricted by voltage considerations, whereas with the O.I.S.C. type there are no such voltage limitations owing to the high insulating and self-healing properties of the oil. Hence we find that the oil-insulated type is used for practically all really high-tension work, and in the opinion of the authors the natural draft type should be confined to very small sizes and low voltages. With the present available materials the economic limit for the O.I.S.C. type is about 1,500–2,000 k.v.a. at 50 periods.

In the remaining types the output, both from a theoretical and practical point of view, is unlimited. Of these types, the oil-insulated water-cooled can be adantageously used only where there is an abundant supply of cheap water at a low temperature. When cheap water is not available air-blast types should be used for large units. The ordinary air-blast type without oil insulation is the one that has hitherto mostly been used under such circumstances, but its safe application is limited by voltage; and further, this type is dependent on the continuity of the air supply, since if this fails the transformer would in a very short time attain a dangerous temperature. On the other hand, the oil-insulated air-blast type, as well as the oil-insulated water-cooled types, owing to the large thermal capacity of the oil, can carry their full load without injury for a considerable time should the air or water supply fail.

With regard to the safe-limiting temperature conditions for transformers, it is important to keep this down as low as possible, since the depreciation of insulation and ageing of iron depends on the temperature attained. This temperature should not for any length of time exceed about 85° C. (German Normalien 95° C., A.I.E.E., 75° C. at full load, and 90° C. at overload.

With transformers of the forced cooled type the temperature of the cooling medium (air or water) can usually be easily kept low enough, and the air temperature of the transformer chamber is of secondary importance. In the self-cooled types, however, particularly for large units, special precautions must be adopted to ensure adequate ventilation of the transformer chamber.

Insulation.—A matter not less important than temperature is that of insulation. Broadly speaking, there are two considerations to be observed which apply to all types of transformers. The external insulation usually gives very little trouble, but the insulation between the various parts of individual coils requires careful consideration. It must be remembered that during sudden changes of potential the voltage across the terminal portions of the high-tension winding may for a short time be raised to many times the normal value, so that for large transformers for really high voltages it is becoming standard practice to specially insulate the end turns, except in such cases where the necessary protection is afforded by heavily insulated choking coils arranged outside the transformer in series with the high-tension winding. In the case of oil-insulated transformers of very high voltages, say, of 100,000 and upwards, the principal insulation difficulty is not in protecting the windings, but in bringing the terminal conductors safely out of the transformer case. This problem is somewhat the same as that of insulating a high-tension cable, except that there is the added difficulty of obtaining sufficient creepage surface in the limited distance between the transformer terminals and case. A form of terminal insulation which has been latterly introduced for dealing with this problem in very high-tension transformers consists of alternating cylinders of insulation and metal foil wound on to a metal tube which constitutes one of the terminals. The consecutive layers of insulation are of similar material and thickness, and the metal foil cylinders have each approximately the same area, so that in accordance with the law for condensers of similar capacity in series, the potential gradient across the entire dielectric thus composed will be uniform. This permits an economy in the total radial thickness of material required, and prevents the greater part of the stress falling on a small thickness of insulation nearest the terminals. In laying out the windings so as to ensure the best disposition of insulation, care must be taken not to lose sight of their mechanical rigidity.

While under normal working conditions the mechanical stresses will be very small, these may become appreciable during transit and erection, and especially also after the transformer is in service in case of short-circuits on the secondary side. This point in the design of transformers has not until recently received the attention it deserves, and even in some modern designs by prominent makers no provision has been made for dealing with such stresses. It must be remembered that the electromagnetic stresses developed are proportional to the square of the current flowing, and in modern transformers having very close regulation at low power factor the current on short-circuit may be from 50 to 100 times the normal full-load current, corresponding to 2,500 to 10,000 times the normal stresses. For instance, in the case of 0·1200-k.v.a. three-phrase transformer having a close regulation, the forces tending to displace the winding were calculated to be 2·8 tons for the coil nearest to the yoke. Fig. 3 shows a construction adopted for taking care of these stresses. In this 1,700-k.v.a. transformer, which has not a specially close regulation, the forces on short-circuit are calculated to be about half this amount. It will thus be seen that the tendency for obtaining closer and closer regulation for transformers is a somewhat dangerous one, especially if the size of the power plant is such that the voltage is maintained if a short-circuit takes place on the secondary side of the transformer.

Mechanical Features.—The following comparison of the mechanical features of the various types was then given. The rectangular shell type affords a sound mechanical construction embodying a short iron circuit, easy method of building, all joints interleaved, freedom from humming, and no bolts are required through the laminations. The rectangular core type is constructed either on the same general lines as the shell type, or it may be built on lines which conform more readily to the general ideas of core-type transformers. In the latter case the cores and yokes may be interleaved or arranged with a butt joint between them, and with this type either concentric or sandwiched windings may readily be used, whereas in the former type the sandwich winding is preferable. For large sizes the circular core type construction requires the use of bolts through the laminations to ensure a really rigid mechanical construction, and is generally built with a butt joint between top yoke and cores, which affords an easier means of assembly and removal of the coils than does the shell or rectangular core type having interleaved joints. With this type either the sandwich or concentric winding may readily be used. Regarding the circular shell type the authors have had no experience in the building of the magnetic circuit, but from the appearance of the finished transformer there would seem to be some difficulty in making a really substantial mechanical job of securing the laminations. With this type probably the triple concentric or sandwiched windings are usually adopted.

Oil Tanks.—The Paper then passed on to the difficulties in the construction of oil tanks absolutely free from leakage, but stated that with suitable materials and design, and expert workmanship, leakage troubles can be satisfactorily overcome. For small sizes of transformers it is customary to use cast-iron tanks, galvanised or enamelled, so as to render them impervious to oil. For larger sizes, sides of corrugated sheet iron have been used, soldered to sheet-iron bottoms, and secured in deep grooves in top and bottom castings, or tanks of plain sheet iron having cooling ribs soldered on outside and inside. The tanks for oil-insulated water-cooled transformers are usually of plain boiler iron construction.

In conclusion, a few remarks were made on fire risk with oil-immersed transformers, a matter which is often much exaggerated.

DISCUSSION.

Mr. J. S. Peck (British Westinghouse Co.), who opened the discussion, agreed with the authors that there was very little difference between the various types of transformers as far as efficiency and weights are concerned, but there were many other considerations which influenced the decision of an engineer in the selection of a type. The possibilities of ventilating and of insulating, of supporting the coils mechanically, of quickly repairing in case of breakdown, adaptability for single-phase and poly-phase construction, for large and small sizes, &c., must all receive careful consideration. In one part of the Paper the author had stated that a high copper loss meant bad regulation, which would have to be compensated for by the use of cable of larger dimensions. There was another point in favour of close regulation, and that was the better light and higher meter readings which were obtained. Regarding fire risk with oil tanks, oil could not be burned unless it was first raised to a high temperature. With regard to the question of explosions in oil-cooled transformers, he had never thought it a very serious risk. He had made a number of tests himself, and could get small explosions inside the case, but only under very extreme conditions. Some engineers, however, insisted that their transformer cases should be explosion-proof, and many cases had to be built to stand 150 lbs. internal pressure.

Dr. C. C. Garrard expressed agreement with most of the conclusions expressed in the Paper, but criticised some of the

Digitized by Google

methods by which they had been arrived at. For example, he had always found with the best design of transformer that the induction density was not the same right through the core. In the double concentric core type very low reactance and very good regulation could be obtained without very much subdivision, which was a great advantage from a constructional point of view. Then the number of sandwiches was kept low; and that came in more especially if earth shields had to be provided, and although these were the last things one should put in a transformer, they were sometimes specified. The great advantage of the "Berry" type of transformer is that the core is kept cool, but, as pointed out in the Paper, the winding was apt to get hot. As regards the explosion effect, what was much more dangerous in transformers was not the explosion due to the oil, but the explosive mixture which was formed, due to the varnish which is used for insulating purposes. The varnish used nowadays consisted generally of compound dissolved in benzine. If a transformer was opened after it had been in use, and not ventilated, an explosive mixture due to the benzine was often obtained.

Mr. K. VON KROGH made some remarks emphasising the important effect of the latest brands of steel alloys in rendering it possible to reduce the size of transformers of a certain output without diminishing their efficiency.

Mr. G. HARLOW spoke of some practical considerations which favoured the adoption of the rectangular shell type of transformer. As the manufacture was cheaper, more material might be put in for the same price, and correspondingly higher efficiency, or for the same efficiency a cheaper transformer could be built. Working at the same induction the shell types had only approximately 60 per cent. of the number of turns of the core type transformer. Thus the labour to be expended on winding was cheaper with the shell type, and this advantage was particularly noticeable in high-tension transformers. A further advantage of the rectangular shell transformer in connection with high-tension work was the ease with which series-parallel connections could be made. Further, the shell type transformer could be much more easily braced to withstand the forces which occur on short-circuit. Another advantage of the shell type was that there need be no bolts through the magnetic core, even in large sizes, and consequently the building of the iron circuit was much cheaper and the possibility of humming was much reduced. He then referred to the advances that have been made in transformers due to the introduction of alloyed sheet steel. These reductions in size and price were, however, not possible for transformers having a lower periodicity than approximately 30. Below this periodicity it was not possible to increase the induction as at present used in low periodicity transformers built with normal iron, owing to the excessive no-load current which results from any increase in this induction. Consequently what might be expected and was obtained in low periodicity transformers due to alloyed steel was a considerable increase in efficiency, but very little reduction in price. The rating with the alloyed steels was entirely limited by the large no-load current, resulting when inductions higher than 14,000 were used, at which induction the no-load current was approximately 10 per cent. Unfortunately the new alloyed steels were no better with regard to permeability than the steel hitherto used. Consequently, in order to still further cheapen the production of transformers having a reasonably high performance, the crying need of the transformer builder is an alloyed steel having the same losses as those recently produced but having a much higher permeability at inductions between 14,000 and 20,000 lines per square centimetre.

Mr. J. N. C. HOLROYDE wished to point out, from a user's point of view, that the troubles experienced with transformers were often due to the carelessness and ignorance of those who handled them, and not to defects in the transformers themselves, and related a number of amusing instances.

Mr. C. F. SMITH thought that the cooling qualities of the circular shell type had been rather underrated. The author had given the best relation between the copper and iron losses plotted as a curve, on a basis of the transformer load factor, with the price per unit at the station given below. It seemed to him that although the method employed by the authors for getting the theoretically correct ratio between the losses would be right if the losses exerted any appreciable influence on the output of the station, this was not the case for very small loads. Considering how small the iron losses were, he thought that the load factor which should be taken was that of the station rather than the load factor of the transformer.

Mr. A. P. M. FLEMING first replied to some of Dr. Garrard's criticisms of the data taken for the theoretical calculations. As an advantage of the circular core type of construction had been claimed the small reactance in the double concentric type of winding used with this type. In this connection he mentioned the difficulty in obtaining a really good mechanical construction for supporting the double concentric windings. The type of transformer which a company started out to build was usually the one they stuck to, as changing over from one type to another meant a large outlay, and this generally gave manufacturers a bias in favour of their particular type. In regard to earth shields, this was a matter in which all designers and manufacturers of transformers agreed with Dr. Garrard. Another very interesting point was the question of an explosive mixture formed due to the use of varnishes containing volatile matter, particularly benzine. Trouble due to this was not, he thought, very likely to occur when baking varnishes were used, which were dried at a fairly high temperature for many hours. The effect of frequency on the types did not alter the comparison already drawn, and with regard to the induction at different periodicities with transformers of, say, 40 periods and upwards, this could usually be increased, using the alloyed iron. When dealing with 25-period transformers, the price could not be reduced by using alloyed iron. In some cases, however, the efficiency could be considerably increased for a comparatively small increase in cost. In reply to Mr. Smith, the "free" iron surface in the circular shell type was smaller than in the case of the other types. It had been particularly pointed out that the cooling of the iron in this type was superior to that of the other types, due to the added cooling surface.

The "Telewriter."—The Postmaster-General has granted a licence for twenty-one years to the owners of the "Telewriter," an instrument for electrically reproducing at a distance handwriting and drawings. The "Telewriter" Syndicate is about to form a company, and will commence the establishment of public "Telewriter" exchanges in connection with the existing telegraph offices next year. The apparatus, which is already in use in several business houses, comprises a pencil used by the writer, the motion of which is resolved into two component motions. By means of two rheostats, controlled by these motions, two currents of varying strength operate magnetically on two levers attached to the receiving pencil, which reproduces completely the motion of the transmitting pencil. The Post Office has granted the use of existing telephone lines, and has undertaken to provide new lines when necessary, but will levy a royalty on the profits of the company, will charge rent for the lines, and has reserved to itself the right of buying the undertaking at fourteen years' purchase.

The Aluminium Corporation.—In the Chancery Division, on Friday, a motion for the appointment of a receiver and manager at the instance of a mortgagee to enforce a security was heard before Mr. Justice Eve. The plaintiffs were Lloyds Bank, Ltd. It appears that the bank has advanced the Corporation £26,200 under the terms of a trust deed, and that on November 26th £24,000 was due for principal, and £312 for interest. Having heard that judgment in another matter had been entered against the Corporation, and that execution was threatened, the present action was taken. During the proceedings it was stated that at the present time there are 110 tons of aluminium in stock at the company's North Wales works, and a quantity of material capable of making a profit of £2,500. The company, it was further pointed out, had favourable contracts in hand, and Mr. Justice Eve appointed Mr. Hawkins, the secretary, receiver and manager for the purpose of working out the material at the works.

Wireless Telegraphy and Telephony.—A new wireless telegraph station for the General Post Office is to be opened to-morrow by the Postmaster-General. It is situated at Bolt Head, near Kingsbridge, in South Devon, and stands some 350 ft. above the sea level. The apparatus installed is stated to be constructed partly under the Marconi patents and partly under certain patents controlled by the G.P.O. It is expected that messages from the public will be accepted for transmission early next year.

Arrangements are being made by the Admiralty for the establishment of stations on the east coast. According to the *Standard*, Ipswich and Cleethorpes have been selected as suitable sites.

The *Figaro* announces that the Minister of Marine has, in a letter to the Academy of Sciences, approved of the establishment of a service of signals from the Eiffel Tower, giving the Paris time to vessels at sea.

Regulations regarding the use of wireless telegraphy apparatus on board of foreign vessels in Norwegian waters have been issued by the Norwegian Government. These require that special permission be obtained before either wireless telegraphic or wireless telephonic communication can be employed in Norwegian waters, that the place and time of operation may be limited, and that the use of such apparatus is to cease immediately at the request of the Admiralty or authorised persons. No vessel lying in a Norwegian harbour within 5 kilometres of the nearest telegraph station may use its wireless apparatus for communication except to prevent disasters. Intercommunication between foreign warships in Norwegian harbours is allowed, however, under the conditions above mentioned. In all cases the provisions of the International Telegraph Convention must be observed.

Further experiments in wireless telephony are being carried out by Prof. Majorana in Italy. Communication was maintained last month between the Island of Laprera and the meteorological station on the Monte Mario, near Rome, a distance of 170 miles, and it is reported that on Thursday last a conversation between Rome and Trapani (Sicily), over a distance of 312 miles, was carried on.

SMALL TRANSFORMERS FOR METAL FILAMENT LAMPS

THE accompanying illustrations show a new pattern of auto-transformer for enabling 25-volt metal filament lamps to be used on ordinary alternating current supply circuits, which has recently been placed on the market under the name of the "Fulmen" auto-transformer, by Messrs. J. L. Cateaux & Co., of 10 Bush Lane. These transformers, which are of simple mechanical design, are entirely British-made, and advantage is taken in their construction of the magnetic qualities of the

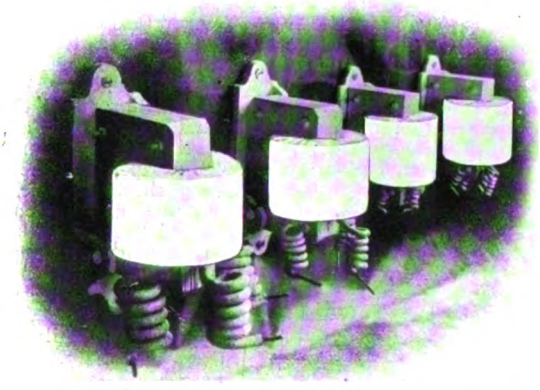

Fig. 1.—"Fulmen" Auto-transformers, House Service Pattern.

finest brands of transformer steel procurable. In their electrical design special attention has been given to efficiency, close regulation, and high insulation. In Fig. 1 is shown the house service pattern, which can be supplied either with a single pair of secondary terminals or for two or more balanced secondary circuits. With the latter arrangement a smaller transformer can usually be employed for the same number of lights, as the size is governed by the maximum out of balance load. In the case of shop lighting, office lighting, &c., where the lamps are turned on at dusk and turned off at closing time, a switch should be fitted, so that the transformer can be switched off at

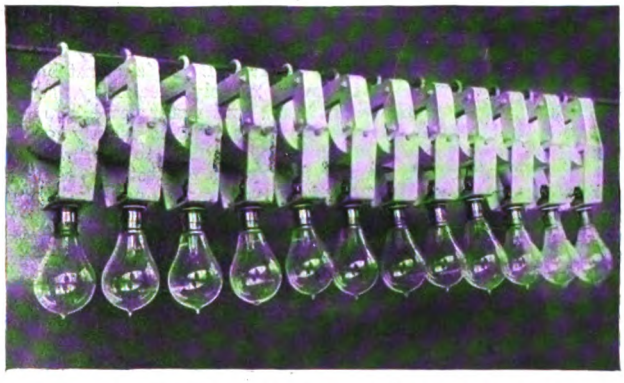

Fig. 2.—"Fulmen" Auto-transformers, Street Lighting Pattern.

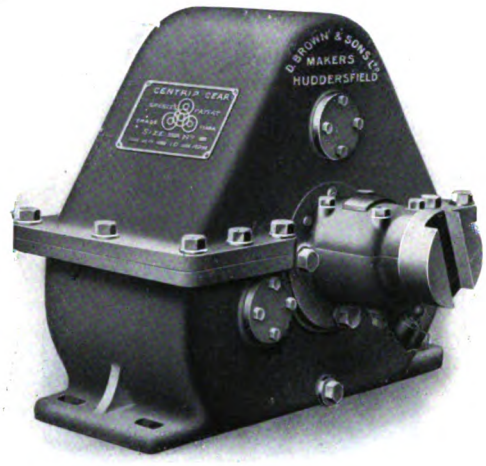
closing time, and switched on again when light is required the following day; by doing this the open circuit losses will be a negligible quantity and the maximum saving in current consumption will be obtained. Fig. 2 illustrates another type of transformer which has been specially designed for street lighting purposes, and is intended to be hung inside the lantern hood. It can either be fitted with one or two lampholders.

A NEW REDUCTION GEAR FOR MOTORS

A NEW form of self-contained reduction gear for use with electric motors where speed reductions of from 10 to 1 to 20 to 1 are required has been put on the market by Messrs. David Brown & Sons, of Huddersfield, under the name of the Spence patent "Centrip" gear. This is a totally enclosed double reduction gear with straight line transmission, and consists essentially of a pinion gearing with three spur wheels, placed concentrically round it and equidistant from one another, which are keyed to shafts on each of which is also fixed a pinion which gears with a spur wheel whose axis is in line with that of the first pinion. The gears are mounted in a case which serves as an oil bath.

The primary nickel steel shaft runs in ball bearings, and is provided on its outer end with a flexible coupling to prevent any possibility of a bending strain being placed upon the shaft, and on the inner end is cut a pinion which gears with three spur wheels fixed to counter shafts placed concentrically around the primary shaft at 120° to one another. The counter shafts are placed one above, and two below, the centre line of the primary shaft, forming an equilateral triangle, and run in ball bearings. One of the wheels of these counter shafts is keyed solid, whilst the other two are bolted to fixed centres to allow adjustment. The pinions which are cut on the counter shafts gear in their



"Centrip" Reduction Gear.

turn with a spur wheel, which is keyed on the slow-speed shaft to be driven. As this wheel is equally driven by the three pinions it transmits pure torque, and therefore does not require a special bearing in the case for its shaft, the wheel being carried on the overhanging shaft of the machinery to be driven.

The enclosing gear box is in two pieces, bolted together on the centre line of the primary and slow-speed shafts; and its appearance is shown in the accompanying figure. The upper portion is readily removable, together with the counter-shaft and wheels it carries, and the lower half is provided with oil sight gauge and drain plug. A hand hole is provided for inspection and filling with oil. The gears are made in various sizes for maximum powers from 10 to 35 b.h.p.

Newcastle Showrooms of Simplex Conduits, Ltd.—A new branch establishment with extensive showrooms has been recently opened by Simplex Conduits, Ltd., at 61, 63 and 65, High Bridge, Newcastle. A special feature will be the stock of fittings suitable for the shipbuilding and colliery industries. The branch will be under the management of Mr. Alan G. Robson, who formerly conducted the business of the Eldon Electric Co., now incorporated with Simplex Conduits, Ltd. At the formal inauguration of the premises on November 12th a number of engineers well known in the North were present, and the com-

Newcastle Showroom, Simplex Conduits, Ltd.

pany, to the number of about 70, dined together at Tilley's Restaurant in the evening, with Mr. Henry Huggins in the chair. The speakers included Mr. J. E. Lloyd Barnes and Mr. Edgar Cross, and Mr. Waterhouse replied on behalf of the company. A very successful musical and humorous programme was provided. The accompanying illustration gives a view of the interior of one of the show-rooms.

AN ALTERNATING-CURRENT LIFT CONTROLLER

MESSRS. W. GEIPEL & CO., of Vulcan Works, St. Thomas's Street, S.E., have recently put on the market a new form of "Schureman" lift controller, which has been designed for use with alternating current where the control is by a rope passing through the lift. The controller is made for two- or three-phase motors only, and is adapted for use where the lift is operated through a hand-rope passing through the cage. As will be seen from the illustration, which shows the 10 h.p. size, there is a reversing switch at the top, which is operated by the hand-rope. It has three definite positions, "up," "down," and "off" respectively; no intermediate positions are possible, so that accidental burning of the contacts is obviated. When the switch is closed, the motor starts with all resistance in circuit. This resistance, which is star connected, is cut out by short-circuiting switches operated through a cam shaft which

"SCHUREMAN" ALTERNATING-CURRENT LIFT CONTROLLER.

is actuated by a solenoid. This solenoid contains the only coil in the apparatus, and it is heavily wound with a large margin of safety. The rate at which the resistance is cut out is regulated by the adjustment of a dash-pot.

The arrangement is such that upon the failure of the supply or opening of the reversing switch by the movement of the rope, all resistance is instantly inserted, whilst it is not possible to reverse the direction of running without first inserting the resistance. The switches are of heavy construction with carbon contacts, whilst every part of the apparatus is readily renewable. The resistance material consists of German silver wound in coils, in which a large margin of capacity is provided. The sizes constructed range from 5 to 25 h.p.

P. & O. Batti Walla Society.—The second smoking concert of the season was held at the Great Eastern Hotel on Monday last, with Mr. Walter Riggs in the chair, and was very well patronised. The next informal monthly dinner will take place at the Holborn Restaurant on February 1st, 1909, as the first Monday in January was considered to be too near to the Christmas holidays.

National Telephone Company's Assessment.—An action has been pending between the National Telephone Co. and the Chorlton (Manchester) Union with regard to the assessment of the company's undertaking in that district. Hitherto in the provinces the company has been assessed at the rate of £1 per mile of wire, but the Assessment Committee of the Chorlton Union conceived the idea of assessing according to the earning capacity of the undertaking in their district, a principle that is already applied to railway and tramway lines. Upon the old basis, the assessment of the National Telephone Co.'s undertaking in Chorlton was £2,895, and under the new system this has been increased to £4,491. Originally the company opposed this, and the case was to have been heard last week at the Manchester Court of Session. The company, however, have now withdrawn the action, having, it is presumed, accepted the new principle.

INSULATING MATERIALS AT THE MARSEILLES ELECTRICAL EXHIBITION

ONE of the most complete exhibitions of insulating materials at the recent electrical exhibition at Marseilles was that of W. Weidmann, of Rapperswil, Switzerland. Among the items shown were several moulded pieces of a material composed mainly of asbestos, and intended particularly for high-tension apparatus. This material, which goes under the name of "Cornite," is said to withstand a temperature of 300° C., and under certain conditions a still higher temperature, without appreciable damage. It is also stated to be entirely non-hydroscopic; unaffected by atmospheric changes; mechanically strong, and capable of being ground and polished; and to be unaffected by continuous immersion in oil at a temperature of 70 to 80° C. Plates for preventing the spreading of arcs from circuit breakers, tramway-controller insulating plates, handles, tubes, and washers for high-tension apparatus, and other moulded articles, are made from this material. Another interesting exhibit was a selection of friction cones and pulleys of an artificial leather which, it is claimed, wears down much more uniformly than natural leather, besides being much cheaper than the latter. Press-spahn in various forms, including sheets in thicknesses varying between 0·1 mm. to 15 mm., was also to be seen. Bobbins and field-coil insulating frames of "Amianite," a vulcanised asbestos material, and a large collection of samples of insulating tapes, varnished linen for slot insulation, moulded mica pieces for commutators, and other insulating accessories, including plates made of an asbestos-cement, and specially suitable for the insulating plates of tramway and railway controllers, were also exhibited.

THE PROPOSED TAX ON ELECTRICITY IN GERMANY

IN last week's issue we gave some particulars of the opposition which is being organised in Germany amongst the representatives of the various electrical and gas interests to meet the proposals of the German Government relating to the taxation of electricity and gas. According to the current issue of the *Elektrotechnische Zeitschrift*, the Verein Deutscher Ingenieure, corresponding to the British Institution of Civil Engineers, has drafted a protest, and has submitted it to the Reichstag. The Verband Deutscher Elektrotechniker, which corresponds more or less to our Institution of Electrical Engineers, has associated itself with the movement. The protest, which concludes with an urgent appeal to the Reichstag to reject the proposals of the Government, points out the unjust and unpractical nature of the Bill, and the retarding influence it is bound to have on the commerce of the country, in that it proposes to tax what is equivalent to a raw material. It is unjust because it affects only two forms of energy, namely, electricity and gas, while poor quality furnace gas, steam and water power are free; also, because the amount of the tax depends merely on the amount of energy used without any regard to the value of the product obtained. Another serious defect is that the amount of electricity generated is taxed, and not the amount usefully applied, which in some cases may be less than 40 per cent. of that generated. The extension of the use of electricity and gas for power purposes in the mining and metal industries will certainly be retarded, and it is stated that the electrochemical works would not be able to compete with foreign works were the Bill to become law. The possible retrogression in the hygienic and social conditions of the people consequent upon a return to the earlier methods of lighting and heating is also commented upon, and it is stated that the revenue from these sources will fall considerably below that estimated owing to the reduction in the consumption of the two commodities which is certain if the Bill becomes law. Some of the almost insurmountable difficulties which will arise in the administration of the tax are then enumerated, among which are the measurement of large quantities of gas; the determination of the calorific value, which in some cases is continuously varying; the determination of the works' costs in the case of both supply stations and private plants; and the disputes that will arise on these questions between the Government officials and the industries. The necessity of a large body of expert officials conversant with the technical features of all kinds of generating plant is also emphasised, and it is claimed that this and other unforeseen expenses of administration, together with the diminished revenue as above stated, will cause the financial benefit to the State to be much outweighed by the general disadvantages to the industries concerned and the country at large.

Comparison of Natural and Induced Draught Systems.—In our account of the discussion on Mr. W. N. Y. King's Paper, on page 734 of last week's ELECTRICAL ENGINEERING, the author is reported to have placed the life of an induced draught fan outfit at about ten years. Mr. King kindly points out that this should really have been about 20 years, as he had known of actual cases of fans which had been running eight or nine years which would last in all probability as long again.

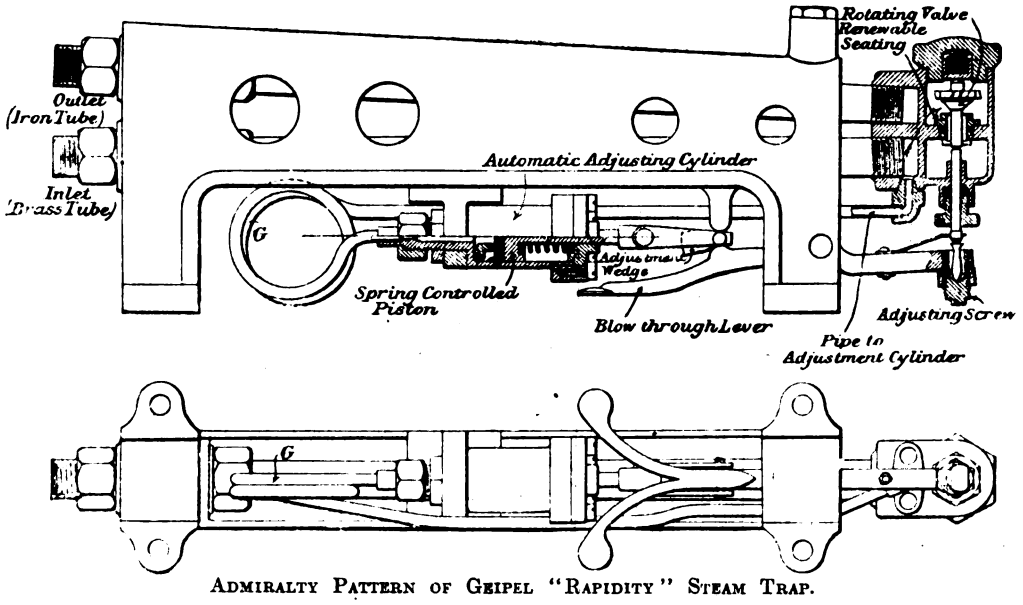
THE GEIPEL "RAPIDITY" STEAM TRAP

ALTHOUGH the Geipel steam trap for the automatic draining of steam pipes is well known in the form which has been on the market now for 10 years, the improved pattern, which was introduced this year, and which differs in some important respects from the old pattern, may not be familiar to our readers, and the following description will therefore be of interest.

The principle of the trap—namely, the contraction of a brass tube when the live steam in it is replaced by condensed steam—remains the same, and the main feature of the Geipel trap, which consisted in the multiplication of the contraction without the use of levers or cranks, is also retained in the new pattern. The point which distinguishes the new "Rapidity" trap from the old pattern is the fact that the valve is arranged so that it is held on its seat by steam pressure, instead of by means of an abutment against steam pressure as in the former pattern. There is thus no continuous strain on the expansion parts. The construction of the trap is shown in the accompanying figure.



ADMIRALTY PATTERN OF GEIPEL "RAPIDITY" STEAM TRAP.

It will be seen that the brass tube which forms the inlet, and is connected to the vessel or pipe to be drained, is at the bottom of the trap, and the iron tube which constitutes the outlet is at the top. In the valve body a passage leads from the entrance of the brass tube to the upper side of the valve, whilst the passage from the lower side connects to the iron tube; the pressure therefore comes on the top of the valve. When the trap is cold or full of water, the brass tube is contracted, so that the valve casing is accordingly pulled into its lowest position, and the valve spindle, which abuts against the lever, is in contact with the valve, and has raised it from its seat. When steam enters the brass tube, the latter expands and moves the valve casing upwards. The steam pressure closes and holds the valve tight on its seat, until water has again entered the brass tube and caused it to contract and again pull the valve casing downwards. Just as the valve opens, a rush of water takes place, which forces the valve upwards, and causes a large opening, and, therefore, a rapid discharge, whilst at the same time the rush of water catches the vanes provided on the periphery of the valve, and accordingly causes it to rotate and grind itself in at each discharge. A sharp blow through occurs at each opening until all the water is discharged, after which the valve is suddenly closed. This prolongs the life of the valve, because of the absence of that cutting action which occurs when water or steam are leaking through improperly opened valves. A lever for blowing through by hand or by foot is provided.

Although the "Rapidity" trap works with considerably greater ranges of pressure than the ordinary Geipel trap, yet, for the purposes of the Admiralty, who specify that a trap must be capable of working from atmospheric pressure up to 300 lb. per sq. in. without adjustment, Mr. Geipel has introduced a new means of automatic adjustment, which is illustrated in the figure. It consists of a cylinder, which is connected to the pressure side of the valve casing by the coiled tube *G*. The steam pressure on the piston is opposed by a helical spring, and the adjustment wedge moves outwards or inwards, according as the pressure rises or falls. This has the effect of raising the abutment by means of which the valve is opened. The higher the pressure at which the trap is to work, the higher is the position taken up by the valve casing, and the angularity of the wedge is adjusted so that it gives the precise movement required by the abutment to accommodate itself to the respective positions of the valve casing. Thus, if the steam in the pipes were at a low pressure, and consequently at a low temperature, the valve body would descend owing to the contraction of the brass pipe, and the valve spindle would strike the abutment, thus keeping the valve open and allowing steam to escape. The piston in the adjusting cylinder, however, is pushed back against the low pressure by the action of the spring, and as the wedge is pulled back, the abutment falls. It then requires a further cooling of the brass tube, caused by the collection of condensed steam in the tube, before the spindle will strike the abutment and open the valve.

Some of the advantages which are claimed for the new pattern are as follows: The range of pressure through which the trap operates without adjustment (and without the automatic adjusting device) is greater than in the former pattern; the valve seat is readily renewable, and the valve casing is easily cleaned by removing the valve and blowing through; finally, the action of the trap is intermittent and without dribbling. A demonstration of the action of the new pattern of trap was given on Friday last at the works of the makers, W. Geipel & Co., and there it was shown that a 1½-in. trap working under a pressure of 200 lb. per sq. in. could discharge one gallon of water in three and a half seconds, the valve closing directly the live steam reached the valve end of the brass tube, so that practically no steam is lost. The small surface exposed to the atmosphere ensures a very small loss due to condensation of steam in the trap itself.

London Electric Supply Bill.—A deputation of London Liberal members of Parliament waited upon the President of the Board of Trade on Thursday in reference to the terms of the London Electric Supply Bill as amended by Sir Luke White's Committee. The purchase terms now in the Bill were strongly protested against, and Mr. Churchill, it is understood, agreed to move an amendment absolutely limiting the terms of purchase to those of the Electric Lighting Act of 1882. At the time of going to press, however, no notice of this amendment had appeared in the Parliamentary papers. We are able to state, further, that in addition to a few drafting amendments, which are of no practical importance, the promoters have, since the Bill left the Committee, inserted a clause for the protection of the instruments at Greenwich Observatory.

Railway Assessment and Tramway Competition.—In the Appeal Court, on Monday, an action by the Assessment Committee of the Southwark Borough Council against the South Eastern & Chatham Railway Companies' Managing Committee was heard in respect of the basis of assessment of the companies' undertaking in Southwark. The companies claim the right to be placed upon the provisional valuation list for the purpose of assessment, their contention being that since the last quinquennial valuation the earnings of the undertaking have seriously diminished as the result of the competition by tramways, tube railways, and motor omnibuses. The case was decided against the Council in the Divisional Court, and the Appeal Court, consisting of Lord Justices Vaughan Williams, Buckley, and Kennedy, now upheld this decision. In giving judgment, Lord Justice Vaughan Williams relied upon a similar case in relation to the New River Co., in which it was laid down that if by any extraordinary or unlooked-for circumstances the value of the property assessed should be greatly increased on the one hand, or greatly decreased on the other, the then existing assessment ought not to continue, and that the taxes should be levied upon the altered state of circumstances. He thought that in this case the alteration in the circumstances of the earning capacity of the companies had been so permanent and substantial as to bring the case within this category.

PROPOSED SALE OF THE BATH ELECTRICITY UNDERTAKING

A LONG correspondence has taken place between the Board of Trade and the Bath Corporation with reference to the proposed sale of the municipal electrical undertaking to Mr. E. Schenk, representing the Bath and District Electricity Supply Co., the intention being subsequently to transfer the works to the Somerset and District Electric Power Co. The result of the correspondence, however, is that the Board of Trade has refused to proceed with the Provisional Order, for which an application had been made, to carry out the proposed transfer. Negotiations with regard to the proposed transfer had been taking place for about two years, and some surprise is expressed at this decision.

It was contemplated that the transfer should take effect as from March 31st, 1908, at which date the capital expenditure upon the undertaking was £159,423, but the purchase price, as stated in the draft deed of transfer, was £162,939, a difference of £3,516. The deed of transfer also provided that the sinking fund and reserve fund, amounting together to £36,000, should remain the property of the Corporation, thus the Corporation contemplated making a profit on the sale of £39,516. The Board of Trade regard it as contrary to practice on the transfer of an electric lighting undertaking that the undertaking should be charged with any profit accruing to the transfer, inasmuch as full price was being paid for plant which had been many years in use. Another point to which objection was taken was that the transfer was to be in perpetuity, it being pointed out that there are no powers for the Corporation to contract their successors out of the rights of purchase confered by Section 2 of the Electric Lighting Act of 1888. Even if such a clause had been passed, it would have been inoperative. The Board was also in some doubt as to the security the Corporation had in regard to the annual payments of the purchase money by the Bath and District Electric Supply Co. in the event of the works being made over by that company to the Somerset and District Electric Power Co. In spite, however, of very detailed explanations, both by the Corporation and by Mr. Schenk, the Board of Trade have refused to sanction the proposed transfer as pointed out above.

The Board of Trade is to be asked to receive a deputation from the Corporation in reference to the matter.

LOCAL NOTES

ABERDEEN: *Supply for Wireless Telegraphy.*—The agreement between the Corporation and the Admiralty for the supply of electricity to the wireless telegraph station at Stonybridge consists of nineteen clauses, and provides that the Corporation shall have completed all necessary works within six months of the execution of the agreement. The supply will be three-phase current at 100 volts, and the price 3½d. per unit, the Admiralty guaranteeing a minimum payment of £350 annually. The Admiralty will also pay £1,000 towards the cost of laying the necessary cable, and £195, which is the cost of connecting the wireless telegraph station with the power house by telephone. The agreement is for five years from March 31st, 1909, after which it is terminable by either party on three months' notice.

Overhead Wires.—Notification is given of an application by the Corporation to the Board of Trade for consent to the erection of overhead wires for electric lighting purposes in the parish of Peterculter.

AUSTRALIA: *New South Wales: Tramways.*—The report of the Chief Commissioner, Mr. T. R. Johnson, on the working of the New South Wales Government tramways for the quarter ended September 30th, 1908, states that the revenue was £248,504, an increase of £20,014 on the corresponding period of last year in the money earned, and over 3,000,000 in the number of passengers carried; the total number of passengers during the quarter was over 42,000,000. Expenditure amounted to £192,806, an increase of £4,852 on the corresponding period of the previous year. The lines, which are principally worked by electric traction, have a total length of 133½ miles. A number of extensions will shortly be opened for traffic and the construction of other lines commenced.

BELFAST: *Tramway Running Powers.*—At the weekly meeting of the Electrical and Tramways Committee on Monday, a letter was read from Messrs. M'Lean & Sons, solicitors for the promoters of the Holywood tramways, as to arranging mutual running powers over their respective systems. The committee decided to leave the matter in the hands of the manager, Mr. Andrew Nance, and the Town Clerk for conference with the promoters, and report the result.

BIRKDALE: *Street Lighting.*—The Birkdale Electric Supply Co. are carrying out an experiment in street electric lighting by means of a number of 400-c.p. and 160-c.p. Osram lamps. The experiment will extend over three months, during which time the Council will institute a comparison of the respective cost and illuminating power of gas and electric lighting.

BRADFORD: *Tramways to Brighouse.*—General satisfaction is expressed locally at the inclusion of a tramway to Bailiffe Bridge in the Corporation's Tramway Bill next session. If sanctioned, this will open up communication with Brighouse, which at present has a very inadequate direct railway service or an expensive and lengthy, although more frequent, one *via* Halifax.

CLEETHORPES: *The Electric Lighting Order.*—The main provisions of the amending electric Lighting Provisional Order, of which the Council has given notice, are to reduce the number of streets comprising the compulsory area, and to extend the time granted by the original Order of 1900 for the carrying out of the works.

COLWYN BAY: *Tramway Extensions.*—The inhabitants of Old Colwyn are much annoyed by the delay in extending the line of the Llandudno & District Electric Tramways Co. to that village. It appears that the company some time ago agreed to contribute the sum of £3,000 as the cost of the necessary road widenings which were to be carried out by the Council, but the latter require this sum to be paid down before the work is actually commenced. The company refuse to do this.

CROYDON: *Tramway Receipts.*—On the year's working, to date, there has been a decrease in the tramway receipts of £471, whilst the number of passengers carried has decreased by 82,771.

DUBLIN: *Street Lighting.*—A proposal is before the Corporation for the expenditure of £1,550 upon public electric lighting in the North Circular and Drumconda Roads.

FELIXSTOWE: *Diesel Engine Generating Set.*—With reference to the recent advertisement of the Council for a Deisel oil engine and dynamo, it was stated at the last meeting that the Chairman of the Lighting Committee and the Electrical Engineer have visited several towns, and inspected various installations of similar plant, and their general impression is that the proposed engine will be satisfactory. Particular points upon which investigation has been carried out have reference to noise, vibration, reliability, and nuisance.

GOLBORNE: *Electric Lighting Provisional Order.*—The Board of Trade have communicated with the Council with reference to the steps which are likely to be taken by the Council towards putting into effect the Electric Lighting Order of 1905, which stipulates that works in the compulsory area should be completed within two years.

HASLINGDEN: *Electricity Supply.*—Mr. H. W. Handcock (Messrs. Handcock & Dykes) has been instructed by the Council to interview the Accrington and Rawtenstall electrical engineers respecting the present and future supply of electricity for tramway purposes. Mr. Handcock will present a special report, also containing an estimate of the cost of the erection of a power station in conjunction with the new destructor works.

Electric Lighting Provisional Order.—The Town Council has decided to apply to the Board of Trade for an extension of time allowed for putting into force their Electric Lighting Order for 1899.

HESSLE: *Electric Lighting.*—Now that the Hull Corporation have powers to supply electricity outside the confines of the City, the Hessle Council have again approached them in connection with a supply in their district. The Hessle Council has an electric lighting provisional order, and a deputation is to wait upon the Hull Corporation to endeavour to arrange terms for the working of the Hessle order.

HOVE: *Electric Supply Charges.*—The petition to the Board of Trade by the Corporation for a reduction in the charges for electric supply by the Hove Electric Lighting Co. has been decided in favour of the company.

LIVERPOOL: *Proposed Power Sub-Committee.*—A proposal by Councillor Muspratt that a sub-committee should be appointed to control the production and distribution of electric power by the undertakings of the Corporation was defeated.

LLANDUDNO: *Tramway Extension.*—The Llandudno & District Electric Tramways Co. has informed the Council that it is impossible for them at present to make any statement with regard to the extension of their lines from Llandudno West Shore to Deganwy. The matter has been referred to a meeting of the whole Council in order to ascertain whether pressure can be brought upon the company to carry out their obligation with regard to this extension.

LONDON: *London County Council: Tramways.*—The traffic receipts upon the Council's tramways from April 1st to November 28th of this year amount to £1,030,712 from lines worked by electric traction, and £196,105 from lines worked by horse traction, or a total of £1,226,817. The receipts for the corresponding

Digitized by Google

period in 1907 under the same heads were £609,399, £279,007, and £1,088,406 respectively.

London County Council: Tramways.—The overhead tramway system of the Council from Brixton Road to Denmark Hill has now been completed, and the Board of Trade inspection carried out. A through service is worked with the conduit system of the Council, and it is stated that the operation of changing over from the conduit to the overhead system, or *vice versa*, takes but a few seconds, and works very satisfactorily.

Marylebone: Street Lighting.—With regard to the proposal made by the Electric Light Committee of the Borough Council to light certain of the ordinary street lamps within the borough by means of electricity, in the place of gas lamps in use (ELECTRICAL ENGINEERING, December 3rd, page 724), the Council, at their meeting on Thursday, approved the recommendation of the Special Committee appointed to consider the matter, to accept the offer of the Electric Light Committee to light the 1,964 lamps affected in those streets where electric mains are now laid, the existing lamp standards and lanterns being utilised, at a lighting and maintenance cost of £8,650 per annum, compared with £8,818, the amount paid for gas lighting. In 1,114 single-burner lamps will be installed one 50-c.p. Tungsten lamp, 827 double, with two 40 c.p., and 23 triple, with three 40 c.p., which will give an average light 2½ per cent. greater than that now shown by photometric test to be actually obtained from the gas system at present in vogue.

Paddington: Tramways.—The Borough Council have confirmed the recommendation of its Works Committee to offer strenuous opposition to the County Council's proposal to construct a tramway from Harrow Road to Maida Vale, by way of Sutherland Avenue. It is contended that the proposed line would depreciate the value of property in Sutherland Avenue and streets adjacent thereto, and that, as it would not link up any existing tram service, it would serve no useful purpose.

MALVERN: *The Trackless Trolley System.*—The proposal by a private syndicate for the sanction of the Corporation to the introduction of the trackless trolley system has been rejected. The Streets Committee, who recommended that the proposal be not entertained, seem to have been largely influenced by the fact that it would have been necessary to instal additional generating plant to the value of £5,000 to cope with the additional load, and felt dubious as to the commercial success of the omnibus undertaking. In the event of failure, they say, they would have been left with this plant on their hands.

MIDDLESBROUGH: *Electric Supply Undertaking.*—For the six months ended September 30th, the electricity undertaking shows a profit of £539, and Mr. H. M. Taylor, the Electrical Engineer, anticipates an improvement of about £1,000 at the end of the year compared with the position last year. Although, in consequence of the strike, the revenue had decreased considerably, the profits exclusive of interest and sinking fund at the present time are £2,105 against £1,565 last year.

MIDDLESEX: *Extension of County Tramways.*—A petition has been presented to the County Council in favour of extending the tramways from Highgate through Muswell Hill into Southgate. There is, on the other hand, considerable opposition to the proposal.

OLDBURY: *Proposed Tramway.*—The Potteries Electric Traction Co. is to be asked to consider the construction of an extension of their tramways between Oldbury and Blackheath.

OLDHAM: *Tramway Finances.*—A discussion took place at Thursday's Council meeting upon the finances of the tramways department. Complaints were made that the reserve fund for renewals is not sufficient, and other criticisms were levelled at the undertaking. The Chairman of the Tramways Committee said that the Finance Committee had £29,600 for the relief of rates which really ought to have been invested in the tramway sinking fund. He also expressed the opinion that the assessment of the tramways should be reduced by at least £3,000, and that if the Committee got fair play in these matters, the tramways would undoubtedly be run at a profit.

PENMAENMAWR: *Electric Lighting Provisional Order.*—The Board of Trade have communicated with the Council as to the possibility of their taking action in the near future with regard to their electric lighting order. As a matter of fact, the period allowed for the establishment of works has now expired. In a discussion upon the matter last week, it was pointed out that the North Wales Power Co had obtained authority to supply in the district, but has not done so, and eventually the Town Clerk was instructed to prepare a report dealing with the position of the Council and the Power Company in the matter, for the information of the Board of Trade.

ROTHERHAM: *Proposed Electric Lighting Extension.*—The extension of the electric supply system to the district of Wincobank is now engaging the attention of the Electricity Committee. The Borough Electrical Engineer is to prepare alternative schemes for extending the existing mains there or erecting a new power station.

RUSSIA: *Electric Railway.*—A project, for which foreign enterprise is responsible, for connecting St. Petersburg with Finland by means of an electric railway, is under consideration. It is proposed to utilise the Imatra waterfall.

TASMANIA: *Launceston Tramways.*—According to the *Australian Mining Standard*, the Launceston Council have decided to construct tramways on the principle of the debenture system, provided the terms and conditions to be arranged with the London tramways group are satisfactory. Before finally settling the matter the fullest particulars will be placed before the citizens, and a plebiscite taken, when, if the citizens approve, the trams will be undertaken by the London tramways group. The main heads of the agreement are as follows:—(1) A price to be mutually agreed to. (2) Price to be paid to the constructing company by the Council's debentures carrying interest at a rate to be agreed upon, the debentures for the purpose of such payment to be taken at current market rates. (3) The running and maintenance to be undertaken and the profits therefrom received by the constructing company for a period of thirty years, and for a period of two years the company shall be personally responsible for the payment of the debenture interest. (4) During the period that the constructing company runs and maintains the tramways, they shall pay to the Council the interest on the debentures, and a yearly contribution as a sinking fund calculated to extinguish the capital cost within thirty years.

TORQUAY: *Trolley Tramways.*—The National Electric Construction Co. have placed a proposal before the Corporation for the use of the overhead system on the projected tramway extension to Paignton, and have asked for a concession for 42 years. The Council, whilst agreeing to the Bill, of which notice has been given, being allowed to go forward, have reserved their right of opposition to matters of detail, including the system which is to be adopted. At the meeting of the Council last week, when the matter was discussed, it was pointed out that the tramway company have intentions of converting the whole of the surface contact system in Torquay to the overhead system.

WEST HAM: *Street Lighting.*—As the existing contracts with the gas companies for street lighting will shortly expire, the Electrical Committee are to be authorised to submit an estimate in competition with the gas companies.

The L.G.B. Inquiry and Power Contracts.—The Electrical Committee have had again under consideration the L.G.B. inquiry, which was adjourned by the inspector (Mr. Hooper) because the representatives of the Council declined to give information as to the terms on which they supplied current to certain large power consumers. The committee have decided that the Council still decline to produce the contracts, and have authorised the Town Clerk to take such steps as he considers necessary to protect the Council's interests.

MIDDLESEX: *London United Tramway Co.'s Track.*—On Monday a conference was held by the local authorities through whose districts the tramways of the London United Tramway Co. run, for the purpose of considering what steps should be taken to compel the company to keep its track in a proper state of repair. After considerable discussion the following resolution was passed:—"That this conference of representatives whose districts are served by the London United Tramways, desires to call the attention of the London United Tramways to the condition of the tramway tracks, which are frequently out of repair and cause great annoyance and danger to users of the highways; that the company be urged to at once organise a proper and efficient system of repair in order that faults may be remedied as soon as possible after they develop; and that Sir J. Clifton Robinson, the managing director of the company, be invited to attend an adjourned meeting of the conference, to be held at the Council House, Hounslow, on Monday, the 14th day of December, 1908, at 4 p.m."

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ARGENTINE.—The *Review of the River Plate* states that a company is being formed to acquire an hydraulic concession on the Rio Primero, in Cordoba, and to erect a large electric power house. The capital is to be $3,000,000 m/n, and the Spanish Bank is said to be interested in the business.

The Senate of the Province of Buenos Aires have approved the Bill granting a concession for an electric light station in La Plata to Mr. A. Limousin.

CARLISLE.—A Local Government Board inquiry was held on Thursday into an application by the Corporation for sanction to borrow £1,000 for the purposes of the electrical undertaking.

DARWEN.—The Local Government Board has sanctioned the borrowing of £2,960, £460, and £637 for electrical purposes.

HEREFORD.—A Local Government Board inquiry is to be held into an application by the Corporation for sanction to borrow £8,000 for electrical purposes, which includes £2,300 excess expenditure.

INDIA.—*The Indian and Eastern Engineer* states that at a recent meeting of the Secunderabad municipality, an application was read from the Indian & Colonial Development Co. for a

Digitized by Google

concession for supplying electric light to Secunderabad. It was resolved that general approval be given to the scheme, subject to expert criticism.

LONDON: *Hampstead.*—The Finance Committee of the London County Council recommend a loan of £5,900 for electric lighting purposes, repayable as follows:—Mains, £1,787, 30 years; plant, £1,191, 20 years; house services, £2,250, 12 years; and buildings, £672, 7 years; £35 being deducted from the amount which might be sanctioned for mains in order to make a round figure of £5,900.

Stepney.—The Finance Committee of the London County Council recommend a loan of £9,500 for electric lighting purposes, repayable in 50 years, at £3 17s. 6d. per cent. per annum.

Woolwich.—A loan of £2,625 for electric lighting purposes has been completed.

MAIDENHEAD.—An application is to be made to the Local Government Board for sanction to borrow £3,500 for the purposes of the electrical undertaking.

MANCHESTER.—The Electricity Committee invite tenders for the foundation work for 6,000-kw. turbo-generator set, pipe trench, and extensions to air filter house at the Stuart Street generating station. Particulars from the Secretary to the Department (fee £2 2s. returnable), and tenders to the Town Clerk by December 18th.

MEXICO.—The Guadalajara Electric Light & Power Co. (Mexico) intends to construct a new line of electric cables about 130 kilometres (81 miles) long, which will serve as a stand-by in case of accident. These cables will be carried on iron poles. Sub-stations will be erected every 15 kilometres (about 9 miles).

SOUTH AFRICA.—*The British and South African Export Gazette* states that a 500-kw. generator is required for the Bantjes Consolidated Mines, Ltd.

Miscellaneous

ARGENTINE.—The Government is to construct certain telegraph lines in the Pampa Central at a cost of 66,000 pesos (about £5,770).

BIRMINGHAM.—The proposals of the Tramways Committee given in our issue for November 26th, with regard to an application to the Local Government Board for sanction to borrow £92,047, for the purposes of adjusting the capital account in connection with the Corporation tramways undertaking, and for the reconstruction of a number of lines, have been sanctioned by the Corporation.

BRADFORD.—The Corporation invite tenders for the supply and erection of two 3,000-kw. turbo-generators with condensing plant, motor-driven auxiliaries, and steam exhause and circulating pipework. Particulars from Mr. T. Roles, City Electrical Engineer (fee, £2 2s. returnable), and tenders to the Town Clerk by December 23rd (see an advertisement this week).

LIVERPOOL.—The Local Government Board has sanctioned the borrowing of £12,400 for tramway extensions.

MIDDLESBROUGH.—As an experiment the Watch Committee has decided to instal arc lamps in some of the public streets.

SPAIN.—The "Gaceta de Madrid" of November 26th contains a copy of a decree authorising the Diputacion Provincial of Guipuzcoa to arrange for the installation and working, for a period of 35 years, of an inter-urban telephone system in the province. The Provincial Government will be required to pay to the State 10 per cent. of the gross receipts.

URUGUAY.—Señor Ricardo Acosta has been authorised to instal a telephone line 25 km. long from Paso de Manuel Diaz across the River Tacuarembo Grande to Estacion Dañado de Rocha.

A decree has been issued authorising the Government to undertake the working of telephone services, first in Montevideo, and afterwards in the various departments. The plans of Mr. A. R. Bennet are to be accepted for the installation of the service in Montevideo, and he is to make further investigations. Amongst these he is recommended to include the examination of the working of Strowger, Lorimer, and other automatic systems. A Chicago firm have applied for a concession for the installation, but the consideration of their application has been postponed.

A project of law authorising the Junta Economica Administrativa of Rocha to contract with Don Frederico Ribas for electric lighting works in the capital of the department has been issued.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—Addition to factory of the British Ultramarine Co., Sugar House Lane, Stratford.

New ambulance and fire station at the Silvertown premises of the India-Rubber, Gutta-Percha & Telegraph Works Co., Ltd.

School, Fairclough Street (968 places), St. George-in-the-East. T. J. Bailey, Architect to L.C.C. Education Committee, Victoria Embankment.

The Stepney Borough Council's Electricity Department has been asked to furnish an estimate for installing the electric light in the workhouse and infirmary.

N.—School, Shelburne Road, Islington (500 places). T. J. Bailey, Architect to L.C.C. Education Committee, Victoria Embankment.

N.W.—Alterations, Stonebridge Park Laundry, Barry Road, Stonebridge. Estate agent, S. Catling, Wembley Hill Station.

S.E.—School, Cow Lane, Rotherhithe (£14,465). T. J. Bailey, Architect to L.C.C. Education Committee. Builders, Kirk & Randall, Woolwich.

School, Sherington Road, Greenwich (500 places). T. J. Bailey, Architect, as above.

Church, Culmstock Road and Alfriston Road, Battersea. Architects, J. S. Quilter & Son, 1 and 2 Adam Street, Adelphi, W.C.

W.—Laundry at Church-path, Acton, for A. J. Smith, 176 Bollo Bridge Road, Acton.

PROVINCES.

ASTON (BIRMINGHAM).—New blocks, workhouse. Architects, Whitwell & Son, 1 Newhall Street, Birmingham.

BACUP.—Secondary School at Waterfoot (£11,500). Surveyor, W. H. Elce, Town Council.

BERKSHIRE.—Enlargement of Royal Berkshire Hospital (£20,000). Architect, C. S. Smith, 14 Bull Street, Birmingham.

BIRMINGHAM.—Roman Catholic Church. Architects, Nicol & Nicol, 117 Colmore Row.

Council School, Sladefield Road. Architects, Buckland & Farmer, Norwich Buildings, Congreve Street.

Additions, Central Library. H. E. Stilgoe, Surveyor to City Council; builders, W. & J. Webb, 256 Great King Street.

Tramway and emergency station, Miller Street. H. E. Stilgoe, Surveyor to City Council; builder, E. Crowder, 153 Farm Street.

BLACKBURN.—School (£7,218). Lewis Beard, Clerk to Education Committee.

BOURNEMOUTH.—New School (650 places). Architect, A. J. Lacey, Municipal Buildings.

BRISTOL.—Roman Catholic School, St. Nicholas (£3,000). Architect, The Very Rev. Canon Scholes, Basingstoke.

CHATHAM.—New School (£15,000). Architect, H. Dunstall, Chatham.

CHELMSFORD.—School (£20,000). Architects, C. & W. H. Pertwee, Bank Chambers, New Street, Chelmsford.

CHELTENHAM.—Residence (£2,500). Architect, T. Malvern, 21 Winchcombe Street; builder, A. Wilson, Swindon Road.

CHESTER.—Erection of Egerton Street School (£2,621). Builders, J. Mayers, Son & Co., Canal Side.

COLCHESTER.—Offices and new blocks at workhouse. Architect, C. E. Butcher, 3 Queen Street, Colchester.

DARWEN.—School (£7,218). Surveyor, R. W. Smith-Saville, Municipal Offices; builders, Lloyd & Millward, Blackburn Road, Darwen.

DROYLSDEN (ASHTON-UNDER-LYNE).—School, Fairfield Road (800 places). H. E. Clare, Clerk to Lancashire County Council, Preston.

GLOUCESTER.—Mission Hall and Sunday School, Seymour Road (£4,700). Architect, J. Fletcher Trew, County Chambers, Station Road.

Extensions to Shire Hall (£8,000). R. Phillips, late County Surveyor, Shire Hall, Gloucester.

GRANTHAM.—Secondary School, London Road. Surveyor, W. Shackleton, Town Council.

HANDSWORTH.—Isolation Hospital. Architect, T. Richardson, Town Hall, Handsworth.

HARROW.—Secondary School (£16,815). H. T Wakelam, Surveyor to Middlesex County Council.

HASLINGDEN.—A new infirmary and boiler-house is to be built at a cost of £21,048.

HEREFORD.—Additions, Free Library. Architect, J. Parker, City Hall, Hereford.

Secondary School, Cattle Market. Architect, R. Jack, County Hall, Hereford.

HOVE (BRIGHTON).—Catholic Church. Architect, B. H. Dixon, 35 East Street, Brighton.

LIVERPOOL.—The Mersey Docks and Harbour Board propose to introduce an improvement in the electric lighting arrangements at the Alfred and Morpeth Docks at an estimated cost of £960.

RUGBY.—Infectious Diseases Hospital. Architect, T. Willard, Market Chambers, Rugby.

SALISBURY.—Isolation Hospital (£8,000). Architect, H. Goodman, 13 Blagrove Street, Reading.

SHIPLEY.—The question of introducing electric lighting into the Saltaire Institute is under consideration.

SOUTHPORT.—Homœopathic Hospital. Architect, Percy Adams, 29 Woburn Place, W.C.

SWANSEA.—Glyn Vivian Art Gallery (£10,000). Surveyor, Geo. Bell, Town Council.

WATFORD.—Drill Hall, Park Avenue. Commanding Officer.

WEST HAM.—Theatre (£18,000). Architect, Bertie Crewe, 75 Shaftesbury Avenue, W.C.

TENDERS RECEIVED AND ACCEPTED

ARGENTINE.—The *Review of the River Plate* states that the municipality of Florencio Varela has accepted the tender of Messrs. Otto Franke & Co. for an electric light station. The public lighting will consist of 40 arc lamps; price $25 per month.

BLACKBURN.—The tender of the Wigan Coal & Iron Co., Ltd., for the supply of steam and house coal to the electricity works has been accepted.

CAPE TOWN.—An order has been placed with the British Westinghouse Co. for the supply of motors from 3 to 20 h.p. during 1909.

CHATHAM.—The Council have accepted the tender of the British Thomson-Houston Co. for the following incandescent electric lamps:—8 c.p., £3 12s. per gross; 16 c.p., £3 12s. gross; 25 c.p., £3 12s. gross; 32 c.p., £4 16s. gross; and 50 c.p., £8 14s. gross.

COSTA RICA.—It is announced that a contract has been concluded between the Government of Costa Rica and a private company for the construction of an electric tramway between San José and Cartago, which are about 12 miles distant.

EAST HAM.—Messrs. Shadrack having completed the delivery of 900 tons of yard slack under their contract at 11s. 6d. per ton to the electricity undertaking, the firm offered to supply from 350 to 450 tons of this coal at 11s. per ton. This offer has been accepted.

GILLINGHAM.—The tender of the Medway Motor & Engineering Co. has been accepted for the installation of electric light at the naval ward of the Infectious Hospital.

GLASGOW.—The tender of Messrs. Allan Arthur & Ure, at £87 10s., has been accepted for relaying the cables for the electric lighting of the grounds of Ruchill Hospital.

ILFRACOMBE.—The Council has decided to accept the tender of the Gas Company for street lighting for the next five years, for the reason that this tender was £300 less than that of the Ilfracombe Electric Light & Power Co.

LONDON: *London County Council.*—The following tenders have been received for the roadwork and platelaying, exclusive of the supply of rails and special trackwork, in connection with the reconstruction on the conduit system of the existing tramways from the "Britannia," Camden Town, *via* Chalk Farm Road, Ferdinand Street, Malden Crescent, Malden Road, Southampton Road, Fleet Road, Agincourt Road, and Constantine Road, to Hampstead Heath. The tenders also contain provision for the execution of certain paving works outside the tramway tracks in connection with the widening of Southampton Road. Mr. W. Manders (recommended), £35,101; Mr. A. M. Coles, £35,737; John Mowlem & Co., Ltd., £36,343. The chief engineer's estimate was £36,444. Provisional sums, amounting to £2,800, are included in each of the tenders for alterations of pipes, mains, &c., the cost of which works cannot be more accurately estimated beforehand, and a sum of £2,000 is also included for any other contingencies which may arise.

The following tenders have been received for six fuel economisers at the Greenwich generating station:—J. Carter & Sons, £3,360; Edwin Danks & Co. (Oldbury), Ltd., £3,378; E. Green & Son, Ltd. (recommended), £3,874; Goodbrand & Co., £3,935; Roberts Bros., £3,957; A. Lowcock, Ltd., £3,960; Clay Cross Company, £3,990. The estimate of the chief officer of tramways comparable with the above-named tenders is £4,000.

The Highways Committee recommend that Messrs. Mountain & Gibson, Ltd., who have an order for six electrically-propelled stores transport vehicles for use in the tramways department, shall be allowed to sub-let as follows:—(i) to the British Westinghouse Electric & Manufacturing Co., Ltd., the electrical equipments; (ii) to Cammell Laird & Co., Ltd., the axles; (iii) to Hadfield's Steel Foundry Co., Ltd., the wheel centres; (iv) to Steel, Peech, & Tozer, Ltd., the tyres; (v) to the Tempered Spring Co., Ltd., Messrs. Sam Osborn & Co., and Messrs. Ibbotson Brothers & Co., the springs; (vi) to Messrs. William Shaw & Co., and Hadfield's Steel Foundry Co., Ltd., the steel castings; (vii) to Leys Malleable Casting Co., the malleable iron castings; (viii) to the Tutbury Engineering Company and Thornewill & Warham, Ltd., the iron castings; (ix) to Messrs. Player & Mitchell and W. S. Laycock, Ltd., the ratchet brake handles; (x) to Messrs. Player & Mitchell, Messrs. Hoskins & Sewell, and Messrs. William McGeoch & Co., the head lights, lighting fittings, and furniture.

Fulham.—The Council has accepted the tender of W. Edgar at £163 6s. 8d. for the supply of street lighting fittings in connection with the conversion of the whole of the 32-c.p. carbon filament lamps now in use in the borough to 200 volt 75 c.p. Osram lamps.

Woolwich.—The tender of the Cliver Arc Lamps, Ltd., has been accepted for the supply of carbons as follows:—(1) 12,000 pairs 18 mm. by 12 in. long, solid, for Oliver lamps, £84; (2) 40,000 pairs yellow-flame carbons with ordinary core, 7 mm. diameter by 12 in. long, 6·35 mm. by 12 in. long, for Oriflamme lamps, £110; (3) 2,000 pairs carbons, enclosed lamps, 11 mm. diameter by 12 in. long, solid, for Brockie Pell lamps, £4 10s.; (4) 2,000 pairs yellow-flame carbons with metal core for Excello lamps, 9 mm. diameter by 15 in. long, 10 mm. diameter by 15 in. long, £20 12s. 6d.; (5) 5,000 pairs ditto large, soft cores, for Johnson & Phillips lamps, 9 mm. diameter by 15 in. long, 8 mm. diameter by 15 in. long, £18 11s. 3d.; (6) 15,000 pairs yellow-flame carbons with metal core for Oriflamme alternating lamps, 7 mm. diameter by 12 in. long, £42 15s.; (7) 5,000 pairs flame carbons for Excello lamps, 8 mm. by 15 in., 9 mm. by 15 in., £45 6s. 3d. Tenders were also received from the following:—General Electric Co., Ltd., Siemens Dynamo Works, Ltd., Ship Carbons, Ltd., Brockie Pell Arc Lamp Co., Ltd., Sloan Electrical Co., Ltd.

LONGTON. The tender of Mr. J. Walters, jun., Ayshford Street, for the construction of two power-houses at the Corporation sewage farm has been accepted at £285.

SHIPLEY.—The tender of Electromotors, Ltd., at £339 for a 10-in. electrically-driven pump and switchgear at the sewage pumping station has been accepted. The following tenders for steam coal have also been accepted: Messrs. Fyfe, Kemp, & Co., 2,500 tons Bower's smudge, and 500 tons Bower's slack; Messrs. Locke & Co., 500 tons of slack; and Mr. John Wade, 500 tons of slack.

STALYBRIDGE.—The tender of Messrs. G. Robson & Co., of Sheffield, for the supply of a portable track grinder has been accepted by the Stalybridge, Hyde, Mossley, & Dukinfield Tramways & Electricity Board.

TUNSTALL.—The following tenders have been received for the installation of electric light in the Museum:—Barnett & Hyde, £13 10s.; Blackburn & Starling, £18 12s.; Evans & Son (accepted), £12 12s.

WEST HAM.—The Council have received tenders for overhauling the electric light installation at the hospital, and providing for the supply and fitting of transformers to reduce the voltage for the use of metallic filament lamps. The quotation of J. T. Halsey at £57 15s. has been conditionally accepted.

YORK.—The Electricity Committee have accepted the following tenders for stores during the coming year:—Engineer's stores, Messrs. G. Barnett & Co.; general stores, Messrs. Hardy & Holgate.

COMPANIES' MEETINGS AND REPORTS

BLACKPOOL, ST. ANNE'S & LYTHAM TRAMWAYS CO.—In this report for the year to October 31st, 1908, the directors regret that the adverse weather and bad trade caused a shrinkage in the traffic receipts as compared with the two previous years. The net receipts on the company's own lines, however, only show a decrease of £370 for the year as compared with last year, and this is considered satisfactory when compared with other tramways both in this district and throughout the country, showing as they do very much larger decreases. The agreement with the St. Anne's Urban District Council has been amended on terms mutually agreed upon between the Council and the company, and this has effected a saving to the company in its cost of electrical energy. The trustees for the debenture-holders have, upon the recommendation of the directors, intimated their intention of paying 2½ per cent. interest on account of the arrears of interest due on the debenture stock. The meeting will be held at Blackpool to-day.

BURMAH ELECTRIC TRAMWAYS & LIGHTING CO.—The report for the year ending July 31st last, from which it will be noticed that the revenue account shows a surplus of £1,676, against an adverse balance last year of £18. It is with great pleasure that the directors are able to report that the plague, which has been so destructive to traffic, seems now to have disappeared, and the receipts show some improvement. Their growth has been very gradual, as the return of the inhabitants has naturally been slow, but the improvement shown towards the end of the year has been fully maintained and tends to increase. After adding the surplus in hand, the revenue balance amounts to £5,201. In view of the fact that no provision has yet been made for depreciation, the directors propose to start a fund for this purpose by transferring thereto the sum of £5,000 out of this balance, leaving the sum of £201 to be carried forward.

INDIA RUBBER, GUTTA PERCHA & TELEGRAPH WORKS CO.—The accounts for the year to September 30th show, after provision for doubtful debts, a net profit of £52,946.

Digitized by Google

Adding balance brought forward, and deducting £12,500 interim dividend paid in July, there remains a disposable balance of £89,480. The directors recommend a dividend of 15s. per share, free of income tax, amounting to £37,500, making, with the interim dividend paid in July, a total payment of 10 per cent. for the year, and leaving £51,980 to be carried forward. The general business of the company shows an increase compared with the results of last year in certain lines; in others, however, there has been a falling off. The electrical industry has been passing through a period of depression, from which we have not escaped. There has been little doing in submarine cable work, but the company's steamers have had occasional employment during the year and are in an efficient condition. The works at Silvertown and Persan have been maintained in their usual state of efficiency. Since the termination of the financial year the Board, under the authority granted by the special resolution of the shareholders of June 30th last, has issued 12,500 preference shares representing one-half of the amount authorised. These shares are cumulative preference of £10 each, and bear interest at the rate of 5 per cent. payable half-yearly on Jan. 1st and July 1st of each year, the first half-yearly payment falling due on July 1st, 1909. The board regret to state that the Hon. Henry Marsham died in July last. Mr. Marsham had been a member of the Board for twenty-one years and the chairman of the company for seven years. Mr. C. H. Moore and Mr. J. Y. Buchanan, the retiring directors, offer themselves for re-election. The meeting is on Tuesday.

MANX ELECTRIC RAILWAY CO.—The report and accounts for the year ended September 30th show gross receipts amounting to £33,734, and expenditure to £16,733. Adding the balance brought forward from last year, there is a sum available of £18,211. After deducting debenture interest (£9,000), interim dividend of 2¾ per cent. per annum on preference shares paid September 30th, 1908 (£3,580 10s.), and amount placed to reserve for special renewals (£1,000), there is a balance of £4,561, and after providing for balance of preference share dividend due in respect of the year ended September 30th, 1908 (£3,580 10s.), there remains a balance of £1,050 10s., which is carried forward. During the year the capital expenditure has been the sum of £299 14s. 6d., as per detailed Schedule No. 3 overleaf. The net result of the year's working has not been as favourable as last year's; bad trade has prevailed, especially in Lancashire, which has affected the spending powers of the people, and from the middle of August to the end of the season very unseasonable, rough weather was experienced in the Isle of Man, in consequence of which the arrivals in Douglas in September totalled 20,543 (or 32 per cent.) less than last year. Previous to August 15th the receipts were actually slightly ahead of last year. The passengers carried during the twelve months totalled 527,986, as compared with 546,666 during the previous twelve months. The receipts were £33,734, as against £35,345 the previous year; whilst working expenses amounted to £16,733, as compared with £16,772, and the ratio of working expenses to receipts has been 49·6 per cent. in 1908, as compared with 47·4 per cent. in 1907. The retiring director is Mr. Ernest Schenk, who, being eligible, offers himself for re-election. At the meeting on Tuesday the report and accounts were adopted.

WEST KOOTENAY POWER & LIGHT CO.—The report for the year to August 31st shows total receipts amounting to $297,670. After deducting working expenses a net profit of $193,906 is shown. After providing for interest on the recent issue of six per cent. bonds, sinking fund, and dividends on the preferred and common stock, a net balance remains of $52,069. The amount carried forward is $409,731, including the balance brought forward from the previous accounts. The demand for power is increasing, and is expected to continue to increase.

MISCELLANEOUS CITY NOTES

ANGLO-ARGENTINE TRAMWAYS CO.—A meeting will be held at Winchester House, Old Broad Street, London, on Friday, December 18th, at 2 p.m., for considering a scheme of arrangement between the company and the holders of the 6 per cent. debenture stock.

CANADIAN GENERAL ELECTRIC CO.—A dividend of 1¾ per cent. has been declared on the ordinary shares for the three months ending December 31st, being at the rate of 7 per cent. for the year. Last year a 2½ per cent. dividend was paid.

LONDON ELECTROBUS CO.—Applications have been invited this week for an issue of £40,000 6 per cent. convertible first mortgage debenture stock. The stock is secured by a first charge on the whole of the property of the company created by a trust deed in favour of the trustees for the debenture stockholders. Any portion of the stock may be redeemed by the company at any time after three years at £110 per cent. on a six months' notice. The stock is exchangeable at any time within three years for ordinary shares, but if not exchanged it is repayable on December 31st, 1919, at 110 per cent. In the prospectus it is stated that the Brighton Corporation has, since the introduction of the Electrobus, declared an intention not to renew the annual licence for petrol 'buses, and it is further stated that the introduction of an electric omnibus service is under consideration in the following, among other towns:—Glasgow, Harrogate, Cardiff, Torquay, Portsmouth, Oxford, Loughborough, Bath, Salisbury, Liverpool, Sheffield, Edinburgh, and York.

MEXICAN LIGHT & POWER CO.—A circular has been issued setting forth the reasons why the Board decided to abandon the negotiations with the Mexico Tramways Co. for an amalgamation of the two undertakings. The circular in question is a reply to those shareholders who desire that the provisions of the proposed lease should be considered, and has been issued in order to assist the shareholders to form a clear understanding of the questions at issue. The proposed lease involves a transfer to the Tramways Co. of all the properties, assets, and concessions of this company, and of the Mexican Electric Light Co., Ltd., and is irrevocable on the part of the power company, but is revocable on a six months' notice at any time by the Tramways Co. The circular also draws attention to the detailed financial proposals of the proposed lease, all of which, it is alleged, are against the interests of the shareholders of the Mexican Light & Power Co. The committee of shareholders have since issued a statement in which the other side of the question is set forth. This points out that the directors have not dealt in their circular with the question of the company's position should the lease not be entered into. The present contract with the tramways company, who are by far the Light and Power Co.'s largest customers, will expire in the ordinary course within the next three years, and there is grave reason to fear that unless some other arrangements are made, the tramways company will determine to generate its own power. Further, if the lease is not completed, the power company will have to find within the next two years a sum of upwards of $6,000,000 to pay off outstanding creditors and provide for immediate capital requirements. This sum the directors propose to find by means of fresh issues of securities and stock, and the placing of such securities and stock would surely react unfavourably upon the prices of the preference and common stocks of the company. The committee conclude that they are convinced, after careful and mature consideration, that a lease of the company's undertaking to the tramways company is in the best interests, and will conduce both to economies in working and a higher standard of efficiency in the management.

MEXICO TRAMWAYS CO.—The following have been elected to the Board of this Company: Mr. E. N. Brown, President National Railroad Co. of Mexico, and Mr. Julio Limantour, director National Railroad Co. of Mexico, National Bank of Mexico, International and Mortgage Bank of Mexico, and President National Dynamite Co.

MONTEREY LIGHT & POWER CO.—Subscriptions have been invited for an addition of £1,000,000 5 per cent. first mortgage debenture stock at 89 redeemable at par on August 1st, 1949, and secured by trust deed in favour of the British Empire Trust Co., Ltd., of London, England, and the National Trust Co., Ltd., of Toronto, Canada, as trustees, and will constitute the stock a first mortgage and charge upon:—(1) 22 miles of street railway in the city of Monterey and surrounding districts including a valuable concession from the Government. (2) The whole of the issued shares and securities of the Monterey Waterworks & Sewer Co., Ltd. (3) The whole of the issued shares of the Monterey Light & Power Co. (4) The whole of the issued shares of the Monterey Plumbing Co., Ltd. Monterey is the capital of the State of Nuevo Leon, Mexico. It has a population of about 90,000, is a great railway centre and distributing point, and is the first city in Mexico in manufacturing importance. There is at present an electric light service in Monterey supplied by the Monterey Light & Power Co.

SAO PAULO TRAMWAY, LIGHT, & POWER CO.—A quarterly dividend of 2½ per cent. has been declared.

VICTORIA FALLS POWER CO.—With reference to our recent note that an action was pending between the Victoria Falls Power Co. and the Rand Mines, Ltd., in relation to certain contracts for the supply of electric power, it is stated by the *African World* that this action has been withdrawn, and that the differences between the two parties have been overcome, with the result that the Power Co. will supply to the group of mines in question.

APPOINTMENTS AND PERSONAL NOTES

Mr. E. Elvy Robb, who was for seven and a half years Chairman of the Electricity Committee of the Tunbridge Wells Corporation, and is a past Mayor of the Borough, has been selected by the constituency of East Manchester as a prospective Unionist candidate at the next General Election.

The Electric Lighting Committee of Wimbledon Town Council received 71 applications for the position of drawing office and record assistant in the Electricity Department. Mr. David Walker, of Wimbledon, has been selected at a salary of £2 per week.

The Eastbourne Town Council have increased the salary of Mr. H. H. Bowlan, Mains Superintendent, from £2 15s. to £3 per week.

Mr. A. Forbes, who has been acting as clerk of works for the electrical work at the South-Western Hospital of the Metropolitan Asylums Board, has been appointed to take charge of the completed plant.

Digitized by Google

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £65 to £65 10s. per ton (last week, £66 to £66 7s. 6d. per ton).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A meeting of the Mutual Telephone Co. will be held at the offices of Messrs. F. Scott & Co., 6 Booth Street, Manchester, on January 5th, 1909, at 12 noon, for the purpose of hearing the liquidator's account of the winding up.

The last day for receiving proofs in the bankruptcy of E. P. Oliver, Electrical Engineer, carrying on business as Messrs. Newington, Priddle & Co., 50 Great Sutton Street, Goswell Road, London, E.C., is December 19th next. Mr. G. W. Chapman, Bankruptcy Buildings, Carey Street, W., is trustee.

The winding-up of the Isle of Man Tramways and Electric Power Co. has now been completed, and the liquidator has applied for his discharge.

DISSOLUTION OF PARTNERSHIP.—The partnership between E. Townsend and A. Chadwick, carrying on business as electrical and mechanical engineers at 118 Bark Street, Bolton, as Townsend, Chadwick & Co., has been dissolved.

NEW COMPANIES

BATLEY ELECTRIC CARBONISING CO.—This company was registered on November 21st, with a capital of £20,000, in £1 shares, to carry on the business of waste pullers and carbonisers carried on by S. Butterfield at Batley Carr as the "Batley Waste Pulling Co." The subscribers are S. Butterfield, Stanley Mill, Batley, and G. H. Briggs, Blindwell Ings, Ossett. Private company. The number of directors is not to be less than five nor more than eight; the first are S. Butterfield, G. H. Briggs, H. Hey, I. Holmes, and A. D. Smith. Qualification, £100. Remuneration, £5 per annum dividend. Registered office, Bradford Road, Batley.

BRITISH TUNGSTEN LAMP CO.—This company was registered on December 1st, with a capital of £12,000 in £1 shares, to adopt an agreement with the Metallfadenlampenwerk, Berlin, G.m.b.H., and the Syndicate Lamp Co., Ltd., for the purchase of the British and Colonial rights in the metal filament and metal filament lamp which belong to the said German company, and in which the Syndicate Lamp Co., Ltd., have an interest. The subscribers are L. Higginbottom, 14 Broomfield Road, Heaton Moor, engineer; R. Hilditch, 16 John Dalton Street, Manchester, solicitor; T. Dicken Jones, Eastwood, Huyton, manager; T. Walton, 36 Spring Gardens, Manchester, C.A.; T. Johnson, Latrigg, Hulmes Road, Clayton Bridge, architect; E. W. Barnaby, Cliff Cottage, Wilmslow, clerk; W. D. Cash, 21 Marlborough Avenue, Clarendon Road, Whalley Range, Manchester, clerk. Minimum cash subscription, 90 per cent. of the shares offered to the public. The number of directors is not to be less than two nor more than five; the first are A. Wenck, of Berlin; and F. C. Becker, of Purley, Surrey (representing the holders of the German shares), and L. Higginbottom, H. S. Morrison, of 52 Albemarle Road, Beckenham, and T. Johnson (representing the holders of the remaining shares). Qualification, £100. Remuneration (except managing directors), £25 each per annum. For one year from the date of incorporation, every 10 German shares confer one vote; afterwards each such share shall confer one vote. Each other share confers one vote at any time. Registered office, Canada Chambers, 36 Spring Gardens, Manchester.

CAERGWRLE AND DISTRICT ELECTRICITY SUPPLY CO.—This company was registered on November 25th, with a capital of £350, in £1 shares, to carry on at Caergwrle and elsewhere the business of an electric light and power company in all its branches. The subscribers are R. F. Allen, Mountain View, Hope, Flintshire, and H. H. Hughes, Ty-Cerig, Caergwrle. Private company. The number of directors is not to be less than five nor more than ten; the subscribers are to appoint the first. Qualification, £25. Registered by Worthington Evans, Dawnay & Co., 27 Nicholas Lane, E.C.

B. JOHNSON & SON.—This company was registered on November 26th, with a capital of £7,500 in £1 shares (5,000 6 per cent. preference), to carry on the business of mechanical, electrical, and general engineers, manufacturers of agricultural implements, steam, electrical, and other cranes, and other machinery and appliances, iron and brass founders, hardware merchants, &c. Private company. The number of directors is not to be less than three nor more than seven; the subscribers are to appoint the first. Qualification, £50. Remuneration (except managing directors), £150 for first year, and £300 per annum afterwards, divisible. Registered by Lupton & Fawcett, Leeds.

THOMAS KESNOR & CO.—This company was registered on November 26th, with a capital of £8,000, in £1 shares, to adopt an agreement with H. J. Norballe, J. L. Lawson, and G. Lawson, trading as "Thos. Kesnor & Co.," and to carry on the business of electricians, engineers, manufacturers of and dealers in electrical and other machinery and apparatus, &c. The subscribers are J. L. Lawson, c/o Thos. Kesnor & Co., Armadale Road, Fulham, S.W., and W. G. Dunstall, 2 Norfolk Street, W.C. Private company. The number of directors is not to be less than two nor more than five; the first are H. J. Norball, J. L. Lawson, G. Lawson, and W. G. Dunstall. Qualification, £50 shares or stock. Remuneration, 10s. 6d. each per board meeting attended. Registered office, Armadale Road, Fulham, S.W.

MUNSTER ELECTRIC LIGHTING CO.—This company has been registered, with a capital of £2,000 in £1 shares, to acquire the business of general electricians and contractors, electric lighting contractors, &c., carried on by J. Hunter, C. H. Wright, J. O'Keeffe, E. Griffiths, and R. H. Bindless as the Munster Electric Lighting Co. No initial public issue.

NEVILLE KAYE & CO.—This company was registered on November 26th with a capital of £5,000, in £1 shares, to carry on the business of constructors, builders, erectors, and suppliers of electric, hydraulic, steam and mechanical lifts or elevators, engineers, &c., and to adopt an agreement with H. N. Kaye. The subscribers are W. S. Durrant, 25 London Lane, Mare Street, Hackney, N.E., and T. L. Henderson, 11 Victoria Street, Charlton. Private company. The number of directors is not to be less than two nor more than five; the first are G. V. Twiss, J. L. Brooks, and H. N. Kaye (managing director). Qualification, £250. Remuneration (except managing director), £25 per annum dividend. Registered office, Thanet House, 213-2 Strand, W.C.

NEWALLS INSULATION CO.—This company was registered on November 28th, with a capital of £60,000 in £1 shares, to manufacture, deal in, erect and apply materials and appliances for affording insulation or protection from or for heat, cold, light, electricity, sound, blows, vibration, air, water, fluids, gases, emanations or rays, to manufacture, deal in, and apply cork, magnesia, asbestos, silicate of cotton, lime refuse, fossil meal, charcoal, flax and other substances, to manufacture and deal in chemical products and substances, and to acquire or subscribe for shares, debts, or liabilities of Magnesia Coverings, Ltd., and the Washington Chemical Co., Ltd., and to adopt agreements (*a*) with Magnesia Coverings, Ltd., and another, and (*b*) and (*c*) with the Washington Chemical Co., Ltd. The subscribers are F. S. Newall, Castle Hill, Wylam, chemical manufacturer, and G. F. Newall, Castle Hill, Wylam, engineer. Private company. The number of directors is not to be more than five. F. S. Newall is the first. Qualification, £500. Remuneration, £100 each per annum.

NEW TRANSPORT CO.—This company was registered on November 12th, with a capital of £11,000 in 10,000 preference shares of £1 each and 20,000 deferred shares of 1s. each, to acquire from A. W. Gattie, A. G. Seaman, and H. Aldrich the benefit of certain existing inventions for improvements relating to the loading, unloading, sorting, weighing, conveying, and marshalling of goods, merchandise, chattels, books, documents, letters, and the like, and to carry on the business of mechanical, electrical, and magnetic engineers, manufacturers of apparatus, appliances, implements, and machinery, &c. The subscribers are:—H. Aldrich, St. Margaret's Burgess Hill, merchant; A. W. Gattie, 13 Ladbroke Grove, W., engineer; F. H. Preece, 27 Clement's Lane, E.C., engineer; A. G. Seaman, The Narrows, Altrincham, Cheshire, electrical engineer; G. Cose, 17 Tower Royal, E.C., solicitor; C. Ashton Denyer, 17 Tower Royal, E.C., solicitor; G. H. Griffin, Meadowlea, Datchet, Bucks, merchant Minimum cash subscription, £500. The number of directors is not to be less than two nor more than seven; the first are A. W. Gattie, A. G. Seaman, and H. Aldrich. Remuneration as fixed by the company. Registered by Cox and Lafone, 17 Tower Royal, E.C.

R. & R. SYNDICATE.—This company was registered on November 14th, with a capital of £5,000 in £1 shares, to adopt an agreement with Anti-Friction, Ltd., the Antifriction Equipment (Railways), Ltd., and the Antifriction (Foreign and Colonial) Patents Co., Ltd., to promote the new company referred to in the said agreement, &c. Private company. The number of directors is not to be less than two nor more than five. Qualification, £50. Registered by Le Brasseur & Oakley, 10 Carey Street, W.C.

T. REYNOLDS & CO.—This company was registered on November 23rd, with a capital of £10,000, in £1 shares, to adopt an agreement with T. Reynolds and to carry on the business of dealers in and manufacturers of motor-cars, motor and other cycles, gas and electrical fittings, gas engines, gas-producing plant, hardware, builders' requisites, &c. The subscribers are T. Reynolds, 19 High Street, Coventry; Ethel M. Reynolds, Woodside, Tile Hill, near Coventry; and Olive M. Reynolds, Woodside, Tile Hill, near Coventry. Private company. T. Reynolds is sole director for life, with £800 per annum and 50 per cent. of the net profit after 5 per cent. is paid on the shares. Registered by E. T. Peirson & Sons, Coventry.

SOREL LIGHT & POWER CO. (OTTAWA).—This company has been incorporated in Canada with a capital of $500,000.

SPANISH RAILWAYS CONSTRUCTION CO.—This company was registered on November 25th, with a capital of £5,000 in £1 shares, with objects as indicated by the title. Minimum cash subscription, half the shares offered to the public. The number of directors is not to be less than three nor more than 15; the subscribers are to appoint the first. Qualification, one share. Remuneration as fixed by the company.

CATALOGUES AND PAMPHLETS RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering"].

ALTERNATORS.—Messrs. Johnson & Phillips have issued a new leaflet giving prices, sizes, and weights of alternators and accessories.

ARC AND OTHER LAMPS.—New pamphlets are to hand from the Electrical Co., Ltd., of 121 Charing Cross Road, giving illustrations of the A.E.G. "Sunshine" flame arc lamp with accessories, and an entirely new pattern of 3-ampere Nernst lamp, giving 800 to 1,000 c.p. for voltages from 200 to 250 volts. The glowers are said to have a life of 400 hours, and the whole lamp is designed to take the place of an arc lamp where great steadiness of light is essential.

HANDBOOK TO LOUGHBOROUGH.—We have received from Mr. W. H. Allen, Borough Electrical Engineer to the Loughborough Corporation, a small handbook to the town, with descriptive letterpress, a map, and 13 photographic reproductions, many of engineering interest, and including a view of interior of the generating station. This guide has been issued by the Trades' Extension Committee of the Loughborough Town Council.

METAL FILAMENT LAMPS.—A small circular of a size to accompany a letter in an ordinary envelope is being issued by the British Westinghouse Electric & Manufacturing Co., Ltd., to call attention to the economies rendered available by the adoption of Westinghouse tungsten lamps, which can be run at an efficiency of 1·2 watts per c.p. These lamps are now made in sizes from 8 to 12 c.p. at 25 volts, from 10 to 20 c.p. at 50 to 55 volts, from 30 to 100 c.p. at 100 to 125 volts, and in the 50 and 100 c.p. size for 200 to 230 volts.

METAL FILAMENT LAMPS.—A circular from the Armorduct Manufacturing Co. announces considerable reductions in prices for the firm's "Gral" metal filament lamps, and amended discounts to the trade. These new prices have been rendered possible by the completion of the extensions to the works where they are made, which have been necessitated by the enormously increased demand for these lamps.

METAL FILAMENT LAMPS.—One of Messrs. Johnson & Phillips' new series of lists, which has appeared during the week, deals with Osram lamps for voltages ranging from 25 to 260 volts.

SWITCHGEAR AND ARC LAMPS.—A new catalogue has been issued by the Universal Electrical Manufacturing Co., of 14 Station Parade, Queen's Road, Peckham, London, S.E. This consists of some twenty leaflets filed in a cover, each of which gives particulars and prices of some speciality. Lighting and traction switchboards, and also small boards for accumulator installations, are among the items listed. With regard to the former, it may be mentioned that the six main low-tension boards for the lighting and power distribution at the Franco-British Exhibition were supplied by this firm. Other leaflets deal with various patterns of knife switches, clip and switch fuses, fuse boxes, iron-clad switches and fuses, &c. Enclosed arc lamps for series burning, but without shunt coils, are listed; these have an auxiliary coil, which ensures that the lamp does not take more than its share of the pressure. A simple pattern of flame arc is also listed. The remaining leaflets relate to arc lamp accessories, street lighting brackets for metal filament lamps, switch and feeder pillars, and cable-junction and house-service boxes.

TELEPHONES AND CALLS.—Messrs. Marples, Leach & Co. have issued a pamphlet containing a description of an ingenious piece of apparatus, known as the "Adnil" vibratory generator, from which currents from ordinary dry cells or other batteries can be converted into alternating current at any pressure for ringing telephone call bells, sounding electric hooters, and other similar purposes. The apparatus, which is very compact and well thought out, combines a pair of vibrating tongue contact makers, with a small step-up transformer. With this apparatus much smaller batteries can be used than direct or ordinary trembler bells, owing to the much better efficiency of the polarised bells without contacts that can be employed. The same pamphlet contains particulars of loud-speaking telephones, hooters, bells, and other apparatus.

THREE-PHASE MOTORS.—The third instalment of a series of lists of induction motors manufactured by the Oerlikon Company is to hand from Mr. G. Wüthrich, of Oswaldestre House, who represents the British department of the firm. This consists of a pair of cards containing well-arranged particulars of three-phase enclosed ventilated squirrel-cage induction motors, ranging from 1/5 h.p. to 55 h.p. for voltages up to 500 volts at 50 cycles. The previous lists dealt with single-phase and unenclosed three-phase machines respectively. The range of sizes is very complete, and from the particulars given in the lists it is evident that the motors are very compact for their output.

ANNUAL DINNER OF THE BIRMINGHAM LOCAL SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS

THE annual dinner of the Birmingham Local Section of the Institution of Electrical Engineers took place on Wednesday, December 2nd, at the Grand Hotel; the number of members and guests present was about 100, and included several representatives from the parent body.

Prof. G. Kapp (President of the Local Section) was in the Chair, and, after proposing the usual loyal toasts, he gave that of "The Institution of Electrical Engineers." In his speech he referred to the probability of the early inauguration of a system of examination of candidates for admission to the Institution, and the gathering showed warm approval of the scheme. Mr. W. M. Mordey (President of the Institution) replied to this toast, and noted with pleasure the warmth with which the proposal for the new system of admission of candidates was received. He referred to the new home of the Institution, and stated that he considered the financial risk was negligible, whilst the necessity for suitable headquarters was not open to question. Comparing our position in electrical engineering with that of Germany and the U.S.A., he was of opinion that we were well in advance of either of these two countries.

Mr. R. Kaye Gray gave the toast of the Local Section, and hoped Birmingham would soon supply a President. Prof. R. Threlfall, in reply, objected to the system of censorship of Papers by the referees in London, and gave very amusing instances of the disadvantages of this method of procedure.

Major W. A. J. O'Meara (Chief Engineer to the Post Office), in proposing the toast of "The City of Birmingham," referred to the diverse character of her manufactures, and instanced a prayer wheel captured during the Tibet Expedition, which proved to have been made in Birmingham. Mr. R. A. Chattock (Chief Electrical Engineer, Birmingham Corporation), acknowledging the toast, described the commercial lines on which the municipal undertakings were conducted, and said no friction existed between the Electric and Gas Departments.

The toast of the "Electrical Industries" was proposed by Mr. J. F. C. Snell, and responded to by Mr. M. Railing (General Electric Co.). The last toast was that of "Our Guests," proposed in a brief but witty speech by Mr. R. K. Morcom, and acknowledged by Mr. J. E. Kingsbury.

The Electron.—The November issue of the magazine conducted by the employees of the Siemens Stafford Works commences with a portrait of Mr. Alexander Siemens, a short biographical notice of whom also appears. The conclusion is published of a Paper on "High-voltage Transmission and Distribution," by Mr. C. H. N. Chamen, with a report of the discussion thereon. Several original articles are also included, together with particulars of the doings of the various societies, clubs, &c., connected with the works.

Newcastle Local Section of the Institution of Electrical Engineers.—The meeting held at Armstrong College on the 7th inst., was of a strictly informal nature, being occupied by an interesting lantern oscillograph demonstration by Prof. W. Thornton, dealing with the effects produced by the superposition of alternating and direct currents. This was followed by the showing of a series of lantern views showing oscillograph diagrams of alternating phenomena taken from commercial machines by Mr. Davis, and after a discussion which was chiefly of local interest, Mr. Carter proposed, and Mr. Stoney seconded, a resolution of thanks to Dr. Thornton.

The Reorganisation of the American Westinghouse Companies.—According to the *Electric Railway Journal* (New York), the readjustment committee of the Westinghouse Electric & Manufacturing Company, of Pittsburg, announced on November 20th that the modified or substitute plan for the readjustment of the debt of the company had been declared operative. This means that the final stage in the rehabilitation of the company has been reached, and that in all probability the company will be out of the hands of the receivers and turned over to the stockholders very soon. It is stated that counsel will now go ahead with the necessary proceedings for the termination of the receivership, the issue of the new securities, and the restoration of the business to the company, all of which will be accomplished in the near future. It has been unofficially announced that Mr. George Westinghouse will remain the president of the Westinghouse Electric & Manufacturing Co. While the merchandise creditors agreed to accept new stock in the company in payment of their $4,000,000 of claims, the stockholders contribute $6,000,000 of new capital by subscribing that amount of stock at par. The employees, besides making their contribution as stockholders, accepted salary cuts ranging from 20 per cent. to 7½ per cent. The company has been making money steadily since the receivership, and the profits are now $9,000,000. This, with the $6,000,000 cash supplied by the stock subscriptions, gives the company $15,000,000 cash working capital, in addition to which $6,000,000 debts have been funded. The total liabilities consisted of about $29,000,000 funded debt and about $15,000,000 floating debt.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Dec. 3rd, 1908

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

1907 Patents

20,223, **Manufacture of Metal Filaments.** "Z" ELECTRIC LAMP SYNDICATE (*H. Zerning*). According to the process described in this specification, powdered tungsten trioxide is mixed with powdered zinc, and then the mixture is heated in an atmosphere of hydrogen. The zinc oxide formed is removed by heating with hydrochloric acid, and the remaining hydrogenous compound of tungsten is mixed with a binding agent consisting of nitro-cellulose, amylacetate, and castor oil. The liquid produced is squirted into filaments in the usual way. After the filaments have been heated in iron vessels coated with a paste of zirconium hydride and amylacetate, they are sintered by passing a current through them in the usual manner. Five claims.

23,450, **Electrolytic Prepayment Meter.** E. SCHATTNER AND R. AMBERTON. In electrolytic prepayment meters, the supply ceases when the level of the electrolyte falls below the level of one electrode. According to this invention an auxiliary electrode is connected in parallel with the above electrode, but through a resistance. The auxiliary electrode remains in the liquid after the main circuit is broken, and so the lamps are only dimmed instead of being extinguished. Two claims, one figure.

28,483, **Dynamo for Petrol Electric Systems.** W. A. STEVENS. The object of this invention is to ensure rapid excitation of the dynamos of petrol-electric systems, and consists in making the magnet poles of the dynamo of soft permeable magnetic steel and hard steel of great retentivity, alternately. Each pole is excited in the usual manner, and the action of such a machine will be normal, except that when the dynamo is running very slowly, it will not lose the whole of its excitation, and further, that the excitation will rapidly increase with an acceleration in speed, owing to the large amount of residual magnetism. Two claims, one figure.

1908 Patents

5,416, **Manufacture of Metallised Filaments.** BRITISH THOMSON-HOUSTON CO., LTD. (*General Electric Co., U.S.A.*). This invention relates to the manufacture of metallised carbon filaments, and consists in impregnating the rough filament with sodium chloride previous to carbonising. It is stated that filaments treated in this way are free from spots of high resistance, and are more uniform in cross-section. Three claims.

11,512, **Motor Starter.** SIEMENS BROS. DYNAMO WORKS, LTD., B. G. PAYNE AND E. SCHUPP. The principle of the motor starter with automatic step-by-step motion, described in ELECTRICAL ENGINEERING, October 29th, 1908, page 586, is given in this specification. The switch arm is controlled by an escapement device and an adjustable balance wheel. Six claims, three figures.

12,275, **Electric Flat-iron.** W. EASTMAN AND A. WARNE. This specification describes a flat-iron, in which the heating coils of platinoid are wound on strips of uralite and placed in slots in the heating surface, the sides of the slots being insulated with mica, which conducts heat. A steel plate covers the slots from which it is insulated with mica. The bottom of the slots are insulated with uralite, which partly prevents the heat from reaching the handle and top surfaces. Four claims, three figures.

18,458, **Heating Apparatus.** BRITISH THOMSON-HOUSTON CO., LTD. (*General Electric Co., U.S.A.*). In order to provide a more uniform heating surface in such electric heating apparatus as flat-irons, &c., and to prevent the heat from being radiated from the other surfaces; the heating resistance unit, according to this invention, is insulated from the portion of the heating surface to which it is nearest, and from the other surface, by means of air spaces in the body of the metal. Two claims, three figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

1907 Patents

18,441, PINCKNEY. Electro-magnets.
22,868, BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*). Motor control systems.
24,165, WILLIAMS. Enumeration of telephone calls.
25,361, MATTER. Railway signalling.
25,585, HOPE, SUGDEN, & GARDNER. Interlocked iron-clad switches.
25,624, WALKER. Commutating devices.
25,655, VON SEEMEN. Processes of manufacturing conducting bodies.
25,716, VENNER & GRIESBACH. Control of electric appliances.
27,611, SUMMERS, WOOTTON, HILL, & GREEN. Electrically-controlled locks and latches.
27,792, COX. Electrical switches.

1908 Patents

931, BINKO & PHŒNIX ELECTRIC HEATING CO. Coffee roasters.
1,187, THOMSON (*Kempt*). Electric railway and tramway systems.
1,696, FRANK. Electric heating apparatus.
2,927, HOWARD & COUSINS. Luminous electric heaters.
3,369, THORNTON, CLOTHIER, & A. REYROLLE & CO. Detector for indicating the existence of high voltage.
3,539, THORPE. Time-alarm signalling systems.
4,193, LYON. Controllers for electric motors.
4,964, SIEMENS BROS. & CO. & FERREIRA. Electrically-controlled railway points and signals.
5,029, JOHNSON & PHILLIPS, LTD., & PATERSON. Arc lamps.
7,302, JACOBS & INSELL. Signalling on railways.
8,101, SIEMENS BROS. & CO., & TOPLIS. Method of cooling commutators.
8,522, BERG. Turbo-generator systems.
8,558. DICKMANN. Electric alarm apparatus.
9,101, AMERICAN ELECTRICAL NOVELTY AND MANUFACTURING CO. GES. Vibration meter for wheeled vehicles.
9,237, ALLGEMEINE ELEKTRICITÄTS GES. Devices for protecting transformers, cables, &c.
9,509, MILES. Electric switches.
9,850, BOULT (*Union Switch and Signal Co.*). Electric signalling systems for railways.
10,764, TATE. Storage battery plates.
10,767, TATE. Storage battery plates.
10,768, TATE. Storage battery plates.
11,064, TIMAR & VON DREGER. Motor starters.
11,068, ROUTIN. Electro-mechanical governors for electric generators, and furnaces.
11,118, DANIELLS. Railway signalling apparatus.
12,305, WIKSTRÖM. Hand lamps for signalling.
12,880, HILLIER. Fire alarm system.
13,661, BLOXAM (*Siemens Schuckertwerke Ges.*). Fittings for electric lamps.
14,425, GRAHAM. Telephonic systems.
14,469, RAFFO & RAFFO. Means for signalling between trains on railways.
15,289, HALL. Magneto ignition machines.
15,461, NICHOLSON. Electrically-sounded horns.
17,148, FAGERLUND. Automatic ignition and extinction of lamps.
17,809, BERGMANN. Magneto igniting device.
20,288, Firm ROBERT BOSCH. Terminal for magneto-electric ignition apparatus.
21,470, ALLGEMEINE ELEKTRICITÄTS-GES. Centrifugal pumps.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

1908 Patents

22,873, SIEMENS & HALSKE AKT.-GES. Process of producing tantalum.
24,192, CONRAD. Electric relays.
24,211, SOC. FRANÇAISE D'INCANDESCENCE PAR LE GAZ (SYSTÈME AUER). Manufacture of lamp filaments.
24,212, SOC. FRANÇAISE D'INCANDESCENCE PAR LE GAZ (SYSTÈME AUER). Manufacture of lamp filaments.
24,264, KETTLER. Manufacture of oxygen-compounds of nitrogen.
24,597, WINKLER. Transparent flexible infusible insulating media.
24,823, STEYNIS. Production of ozone.

Application for Amendment

Further particulars and instructions as to procedure in opposition to amendment will be found in the Official Journal of the Patent Office of Dec. 2nd, 1908.

17,248, of 1905. **Electric Power Transmission Systems for Ships and Vehicles.** E. W. HART and W. P. DURTNALL seek leave to amend this specification in order to make the meaning of a certain paragraph clearer.

Expiring Patent

The following patent expires during the current week after a life of fourteen years:—

24,541, of December 17th, 1894. **Electrolytic Apparatus.** DR. CARL KELLNER. Apparatus for the electrolysis of metallic salts, in which the cathode consists of a helical channel of mercury. The mercury continually passes from the decomposing chamber to the combining chamber, and then back to the decomposing chamber to form fresh amalgam.

"Electrical Engineering," although the Cheapest Electrical Paper (Price 1d. weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

THE Bolt Head wireless telegraph station of the General Post Office, which was opened on Friday last, is the first Post Office station which will give facilities for communication with ships at sea, under the provisions of the International Radio-Telegraphic Convention. Most of the apparatus installed in the station is of the latest Marconi pattern, which includes some interesting improvements on former practice. When working, both the transmitting and receiving circuits are connected to the aerial, and the same operator can receive while transmitting. This arrangement is rendered possible by the use of a small spark-gap inserted in the aerial, across which the receiving apparatus is connected. During transmission, the current surges bridge this gap which is then practically non-existent. Means are provided for automatically short-circuiting the telephone when contact is made in the transmitting circuit. A novel feature is the provision of variable couplings in the high-frequency oscillation transformers for the purpose of enabling sharper waves to be produced. The receiving apparatus includes the latest pattern of the Marconi multiple tuner. A mast, 160 feet high, supports an umbrella type aerial of stranded copper wire. (Page 777.)

THE Comptroller-General of Patents has issued an Order that two patents covering a manufacturing process, which is being carried on exclusively outside the United Kingdom, are revoked. This is the first decision under the revocation clause of the Patents and Designs Act, 1907. In order to avoid revocation the patentee would have had to show satisfactory reasons for his omission to arrange for the manufacture in this country. The Comptroller set aside the plea that the manufacture would cost more owing to higher rates of wages, and he also held that the patentee could not relieve himself from manufacturing in this country by the mere insertion of a few advertisements for buyers of the patent or licensees, and the sending round to manufacturers of a few circulars, to which no replies are received. Another point arising out of the decision is that the motives of the applicant for revocation are quite irrelevant to the issue. (Page 780.)

Mr. J. Roberts, of Durban, in his Paper on "Commercial Electric Heating" which was taken as read last Thursday, before the Institution of Electrical Engineers, outlined a proposed system of alternating-current distribution at 800 volts, with house transformers to reduce to 50 volts for both lighting and heating purposes, and described some simply constructed cooking apparatus of his own design for use on this system. (Page 781.)

According to a report by the Highways Committee of the L.C.C., there have been 927 occasions on which the live stud indicators operated on the cars on the G.B surface-contact system in the Mile End Road; 728 of these live studs afterwards cleared themselves, 185 cleared after hammering, and 7 remained alive. (Page 782.)

The Physical Society of London held its annual exhibition of apparatus, in which a number of well-known instrument manufacturers took part, on Friday last. (Page 782.)

A Paper was read last night before the Leeds Local Section of the Institution of Electrical Engineers by Mr. J. W. Beauchamp, in which the methods of keeping records of the positions and nature of mains and services in use at Sheffield, and a proposed more complete system, were described. (Page 783.)

At the Institution of Electrical Engineers, on Thursday last, a Paper was read by Messrs. J. C. Macfarlane and H. Burge, on the present state of the design of electrical machinery, with special regard to the possible output limits at medium speeds from given core dimensions. A large number of generalisations with regard to the design of both continuous-current and alternating-current machinery were made in the Paper, and the results of these were embodied in quadrant diagrams, which expressed the output factors as functions of the core dimensions. The part of the Paper relating to continuous-current machinery concerned interpole machines only. Deep slots, and a low ratio of magnetic to electric loading were advocated in the case of continuous-current machines, and high saturation and small air-gaps in the case of alternators, as means of increasing the output. The view was also expressed that the output of induction motors could be limited by temperature rise only. In the discussion which followed the Paper, Col. R. E. Crompton referred to the disregard of the importance of the core in the early days of dynamo design, and Mr. C. C. Hawkins doubted if generalisations in the design of alternators could yet be safely made. Dr. S. P. Thompson commented on the increasing strength of armatures in relation to the strength of the field system, and suggested a means of decreasing the self-inductance of induction motor windings. The curves given for induction motors were criticised by Mr. Miles Walker, and Mr. G. G. Stoney referred to the improvement in the quality of armature iron. Mr. S. E. Glendenning emphasised the importance of good ventilation. Several written communications have been received. (Page 785.)

Mr. W. R. Cooper's Paper on electricity supply tariffs and electric heating and cooking, read recently in London before the Institution of Electrical Engineers, was further discussed in Dublin last week. The discussion turned chiefly upon systems of charging, and some difference of opinion was shown. It was also generally agreed that neither the cost nor the design of electric cooking apparatus had yet reached finality. (Page 790.)

The third reading debate upon the London Electric Power Bills took place in the House of Commons on Monday, when several important amendments were made. A Board of Trade amendment was made, stipulating that the purchase terms in 1931 should be under Section 2 of the Electric Lighting Act of 1888. Mr. Churchill also stated that a Bill would be introduced as soon as possible constituting the London County Council the purchasing authority for the West End companies in 1931, thus placing all the companies in the same position in this respect. Words were inserted in the London Electric Supply Bill authorising linking up between the West End and East End companies. A clause protecting Greenwich Observatory was inserted in the London (Westminster and Kensington) Electric Supply Bill, a similar clause being already in the London Electric Supply Bill. (Page 791.)

Under Electrochemistry and Electrometallurgy we note the methods for removal of sulphur in iron and steel metallurgy by the old methods, and in the Héroult and induction furnaces. Notes are also given upon aluminium carbide, the number of electrode furnaces employed in the iron and steel industry, and on the Papers read before the Faraday Society. (Page 792.)

Amongst the specifications published by the Patent Office on Thursday last was one by the British Thomson-Houston Co. for a method of obtaining regenerative braking with continuous-current series traction motors. A specification by Miles Walker relates to means for the prevention of sparking due to over commutation, and another by E. von Seemen concerns the manufacture of incandescing bodies of alumina and magnesia for electric lamps. The patent specification for the "Venner" time and solenoid operated main switch combination for the control of arc lamp circuits was also among those published last week. Dr. W. M. Thornton, H. W. Clothier, and A. Reyrolle & Co., Ltd., have obtained a patent for a detector for indicating the existence of high voltage, and three patents granted to A. O. Tate relate to the construction of a novel compound plate for storage batteries, which consists of alternate anode and cathode sections. Among the patents expiring during the current week is one by H. Aron, relating to an electric winding device for clock and meter mechanisms, and another by G. H. Nisbett for sealing boxes for cables. Short abstracts of the above are given in our Patent Record. (Page 793.)

A letter from a Berlin correspondent, referring to Mr. Mordey's recent Presidential Address, states that wages are higher in Germany, and that other conditions result in prices being generally higher. He contends, however, that Mr. Mordey's figures as to the output of the German stations are incorrect, owing to the omission of the outputs of large independent power stations supplying mines, ironworks, &c., and denies that the electrical manufacturing industry in Germany is behind that of Great Britain.—We also publish a letter asking for an explanation of a point in Mr. Devereux's article on the Cardiff telephone exchange, and have appended the author's reply. (Page 776.)

The Engineers of the South Metropolitan Electric Light & Power Co. and the Beckenham Electricity Works are to meet in reference to linking up the two undertakings.—The Local Government Board has now sanctioned the loan for the sub-station at Brighouse, in connection with the supply from the Yorkshire Electric Power Co.—A non-statutory electric light company is to commence operations in Chippenham.—The Dublin Electric Lighting Committee report that the number of units sold for lighting purposes shows a tendency to diminish, owing to the use of metal filament lamps, but much better results are anticipated during the next twelve months.—As the experiment of fitting a smoke prevention apparatus at the Stepney Electricity Works has not proved absolutely successful during the trial period, an extension of one month has been granted to the company whose apparatus has been installed.—There has been a loss of £1,900 and £200 upon the Lowestoft municipal tramways and lighting undertakings respectively for the year to September 30th.—Arbitration proceedings are taking place with reference

Digitized by Google

to the purchase by the Corporation of the Morecambe horse tramways.—Detailed figures have been prepared in regard to the introduction of the trackless trolley system at Newport (Mon.). The adoption of the system is recommended on six routes inside the borough and four routes outside, the total length being about 12 miles.—A writ has been served upon the West Ham Corporation to prevent the payment of interest on an overdraft from the Bank which has not been sanctioned by the Local Government Board.—The Wolverhampton & District Tramways Co. have notified the Corporation of their intention to discontinue the through service between their trolley lines and the surface contact system in the town. (Page 795.)

Five water-tube boilers with economisers, mechanical stokers, &c., are required by the Sydney Corporation. Local Government Board inquiries have been, or shortly will be, held as follows: Dover (£4,600), Eccles (£8,000), Keighley (£12,820), Leyton (£1,299), and Radcliffe (£14,500). The tender of Messrs. Dick, Kerr & Co. has been accepted at £82,715 for the roadwork and plate-laying in connection with the reconstruction of the L.C.C. tramways from Hackney Road to Stamford Hill. (Pages 798–799.)

The report for the year to September 30th of the Underground Electric Railways Co. of London states that the scheme for the conversion of the profit-sharing secured notes, sanctioned by the Court, has been carried into effect. In future half-yearly accounts will be submitted to the shareholders in June and December. An issue of £500,000 4¼ per cent. perpetual consolidated debenture stock of the British Columbia Electric Railway Co. has been advertised during the week. Quarterly interim dividends are announced by the Eastern Telegraph Co., Eastern Extension Co., Globe Telegraph & Trust Co., Great Northern Telegraph Co., and the Western Telegraph Co. (Page 799.)

The letter from Berlin which we publish in our Correspondence Column this week, presents what may be regarded as the German point of view with regard to the matters dealt with in Mr. Mordey's recent Presidential Address. In the first place the writer joins issue with Mr. Mordey on the question of accuracy of statistics, complaining that Mr. Mordey has not taken account, in his comparative figures, of the large amount of power supplied in Germany from independent generating stations owned by groups of mines, ironworks, &c., far exceeding that supplied by non-statutory electricity works in this country. Yet since the aggregate capacity of all the electricity works is given by Mr. Mordey as 9·7 watts per inhabitant in Germany, as against 21·8 watts per inhabitant in Great Britain, it is very improbable that the correction which our correspondent suggests would be sufficient to make up this enormous difference. Mr. Mordey's other figures bear this out, and in addition his figures, showing the cheaper generation of electrical energy in this country, and the lower selling price to the consumer cannot be gainsaid. Secondly, our correspondent insists that wages in Germany are higher than in England, that coal is dearer, and that elegance and roominess of the German central stations is considered more essential there than here. Whether the first point is conceded or not makes little difference, as the wages item is but a small proportion of the total, and the difference in the wages per unit is very small. Again, whether coal be dearer or not, a comparison of the steam consumption per unit would still, on the whole, be in favour of British practice. As to the roominess of engine-rooms and adornment of switchboards, there can be no doubt that this is carried too far in many German stations. Its effect in encouraging the men to keep the machinery in better condition is measurable by the cost of repairs and maintenance, and there is nothing to show that this charge on the undertaking is higher here than in Germany. We cannot concede that we are behind Germany in power-station design, and we are certainly in advance of that country in economical station management. Nor can it be said at the present day that our methods of manufacture are antiquated or inefficient. The depression in the electrical manufacturing industry is not due to backwardness in our engineering ability, but is solely attributable to the commercial side. Although the serious cutting of prices came in the first instance from Germany, we can agree with our correspondent on one point, viz., that, in the selling of electrical machinery at the present time, it is not the German, but the British firms who are the sinners in this respect. There are signs, however, of a slight revival in the industry, and we trust that the increased activity in electric lighting is being followed by an increased demand for electric motors and power plant generally. The approaching completion of the electrical equipment of the suburban lines of the London, Brighton, and South Coast Railway, is being awaited with interest by more than one railway company, and even the Miners' Eight Hours Bill may be a blessing in disguise, as far as electrical manufacturers are concerned, for it will result in a greater incentive to mine-owners to take advantage of the economies rendered available by electrically-driven labour-saving machinery.

The result of the debate upon the London Electric Power Bills in the House of Commons on Monday night is that the London County Council's objection to the "eight company" Bill have been overcome, and as the companies have accepted the amendments relating to the terms of purchase, it may be taken that the question of electric supply in London is now settled, at any rate so far as the companies are concerned, until 1931. For the first time since this matter was first opened, it is now possible to look upon a more or less settled condition of affairs, and as some of our readers may not have had leisure to follow the somewhat complicated proceedings of the present session, a concise statement of the present situation will be appreciated. In the first place, in respect of what are known as the eight East End companies, the London County Council has been constituted the purchasing authority in 1931, with one or two reservations, which are set forth in our report of Monday's debate. The terms of purchase are those of Section 2 of the Electric Lighting Act of 1888, and which are embodied in the various Provisional Orders. The same conditions of purchase will apply to the West End companies, but a Bill will be brought in at an early date, definitely constituting the London County Council the purchasing authority. The companies will be allowed to link-up their undertakings, in the widest possible sense, even to the extent of one company handing over the working of its distributing system to another, a very different thing to the limited powers of linking-up—if they can be called such—under an ordinary Provisional Order. These, together with

Digitized by Google

the power to supply for traction, &c., for use outside the area of the supplying company, are the main objects of the Bill, and the remainder of the thirty-one clauses are simply the machinery necessary for giving effect to these principles. One important matter of detail is the insertion in both the London Electric Supply and the London (Westminster and Kensington) Electric Supply Bills of a maximum price for power users, viz., £6 15s. per kw. of the maximum demand per annum, plus 0·5d. per unit. Whilst this is high, compared with maximum prices in the bulk supply Bills concerning London, length of tenure is an important factor, the present companies having a remaining life of only 23 years against the 42 years proposed in the bulk supply Bills. As pointed out above, the outstanding matter is to constitute the London County Council as the definite purchasing authority for the West End companies, which was prevented from being put into effect by the Committee, owing to a technical difficulty, and when this has been accomplished, all the difficulties and complications surrounding the purchase of the existing companies, which have been a conspicuous feature of the problem since the introduction of the Electric Lighting Act of 1882, will have disappeared.

MUCH interest attaches to the first decision of the Comptroller-General of Patents, under what is known as the revocation clause of the new Patents Act. He has issued an order revoking two patents which are being worked exclusively outside the United Kingdom, and in doing so he has given his reasons at considerable length, so that the document forms a useful guide as to how this part of the Act will be interpreted in similar cases. Of course, until the decision of the High Court has been given upon the appeal which is certain to follow, the case cannot be regarded as a definite precedent to which the manufacturing industries can turn with absolute confidence for guidance, but in the meantime the Comptroller-General's interpretation may be accepted as sound and logical, and one likely to be upheld. It is, in fact, a perfectly literal interpretation, and although he is vested with discretionary powers to determine whether or not the patentee has given "satisfactory reasons" for not having manufactured his patented article here, it is evident that the Comptroller has followed the spirit of the Act in giving his decision. The patent is not an "electrical" one, but the subject of the patent would in any case not have much bearing on the matter, unless some process were in question which it would be practically impossible to carry on in this country on a commercial basis. The plea that it might cost a little more owing to higher wages having to be paid has not been admitted. The owners of the patent also contended that they had honestly endeavoured to make arrangements for the sale of the British patent, or for finding licensees in this country by the insertion of advertisements in technical papers, and by circularising manufacturers who might be inclined to take up the patent in question. This same perfunctory proceeding has been carried out with so many patents that it is interesting to note the Comptroller's view as to the inadequacy of this method of endeavouring to evade the consequences of the Act. He says: "It seems to me impossible to hold that a patentee can relieve himself from the duty of manufacturing in this country by the insertion at any time of a few advertisements, and the sending round to manufacturers of a few circulars, to which no replies are received. The advertisements and offers in this case were, I may say, of the vaguest description; they gave no intimation of the terms on which the owners of the patents were prepared to treat, beyond the statement that such terms would be reasonable." The description in the last sentence might apply to the greater number of patents that were advertised in this way last August, and we pointed out in our issue of September 3rd, the week after the revocation clause came into force, that advertising the patent by title only, and not supplementing the announcement by active personal endeavours to start manufacture in this country, or to find firms to manufacture under licence, would rather prejudice than assist the patentee in attempting to oppose a subsequent application for revocation. Those interested in the question should refer to the issue of ELECTRICAL ENGINEERING mentioned (September 3rd, 1908), as in the same article was set forth the procedure that must be followed by applicants desiring to have a patent revoked.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, DECEMBER 17TH.

Institution of Electrical Engineers.

8 p.m. Meeting at 25 Great George Street, Westminster, London. Paper to be read: "The Electric Discharge and the Production of Nitric Acid," by W. Cramp and B. Hoyle.

Rugby Engineering Society.

8 p.m. Ordinary meeting. Paper to be read: "The Utilisation of Exhaust Steam with Low-pressure Turbines," by E. Halliwell.

FRIDAY, DECEMBER 18TH.

North-East Coast Institution of Engineers and Shipbuilders.

7.30 p.m. General meeting at the Literary and Philosophical Society, Westgate Road, Newcastle-on-Tyne. The discussion on Mr. J. B. Duckitt's Paper on "The Electrical Equipment of Cranes" will be resumed.

Electro-harmonic Society.

8 p.m. Smoking Concert at Holborn Restaurant (King's Hall).

Institution of Engineers and Shipbuilders in Scotland.

8 p.m. Meeting at 39 Elmbank Crescent, Glasgow. Paper to be read: "Standardisation and its Relation to the Trade of the Country," by Sir John Wolfe-Barry, K.C.B., F.R.S.

MONDAY, DECEMBER 21ST.

Faraday Society.

8 p.m. Meeting at the Institution of Electrical Engineers, 92 Victoria Street, Westminster, London. Paper to be read:—"The Influence of Cheap Electricity on Electrolytic and Electrothermal Industries," by E. A. Ashcroft.

Institution of Civil Engineers.

8 p.m. Ordinary meeting. Paper to be read:—"An Investigation of the Heat Losses in an Electric Power Station," by F. H. Corson.

Telegraph Traffic.—The submarine telegraph cable between Zanzibar and Mombassa, which was interrupted during September, October, and November, again ceased working on the 11th instant. A quick repair was effected on the 12th inst., however. The line between Bagdad and Bassorah has failed again.

Wireless Telegraphy.—Regulations relating to wireless telegraphy in the British East Africa Protectorate have been issued recently; these provide that no person may establish any wireless station, or instal any apparatus for wireless telegraphy in any place, except under licence granted by the Governor.

According to the *Financial News*, Signor Marconi is said to have stated that a wireless telegraphic service at a penny per word will shortly be in operation between England and Italy. France, it is said, objected to the scheme originally, as telegrams between England and Italy pass over her lines at present; but has since withdrawn her opposition. It is stated that the service will be commenced as soon as the wireless station at Coltano is completed.

THE BOLT HEAD WIRELESS TELEGRAPH STATION OF THE GENERAL POST OFFICE

THE new wireless telegraph station of the General Post Office, which was opened by the Postmaster-General on Friday last, is situated at Bolt Head, near Kingsbridge, South Devon, and stands some 350 feet above the sea level. Considerable interest attached to the station, as it will be the first to be used in the public service for the purpose of communicating with ships at sea. The other wireless telegraph stations owned by the General Post Office, notably those at the Wash and in the Isle of Mull, were more or less experimental, and did not accept messages for ships at sea. The present station will give public communication with all the ships going up and down the channel that have wireless apparatus, whatever their nationality or system, thus complying with the regulations of the International Radio-Telegraphic Convention of 1906. The normal range of the station is 250 miles.

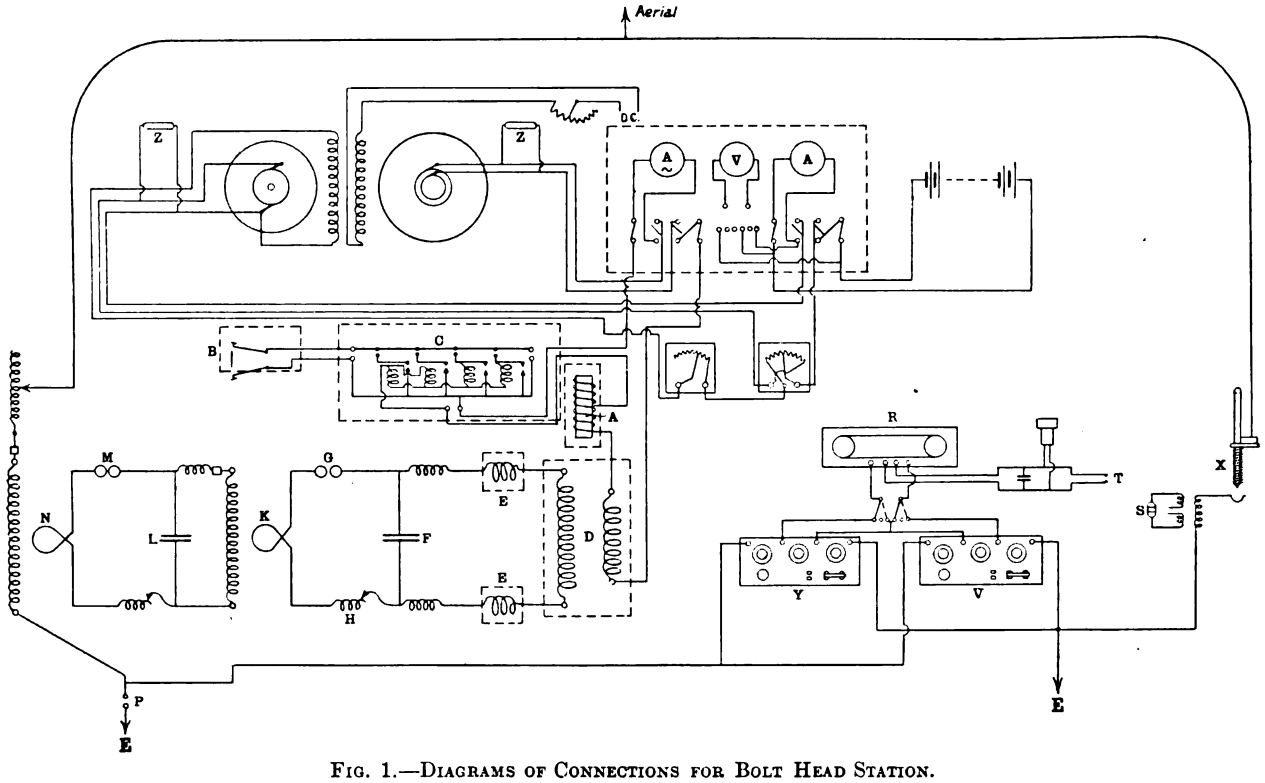

FIG. 1.—DIAGRAMS OF CONNECTIONS FOR BOLT HEAD STATION.

Through the courtesy of Major W. A. J. O'Meara, Engineer-in-Chief to the Post Office, we are enabled to give the following description of the main features of the installation. The generating plant and apparatus for the new station are contained in a one-storey brick building, 15 feet wide by 55 feet long, which has been erected close to the previously existing coastguard station. In order that the plant can be started up immediately when required, and also to eliminate noise as much as possible, the 3-kw. alternating-current generator is coupled to a direct-current machine, which, under normal conditions, is run as a motor from an accumulator battery. To charge the battery, the two machines are driven through a clutch by an 8 b.h.p. horizontal Campbell oil engine, running at 265 r.p.m. Current for the wireless apparatus can be taken from the alternator at the same time. Alternating-current is generated at 100 volts, 50 cycles, and is transformed up to from 15,000 to 20,000 volts, according to the length of the spark gap which is being used. The secondary pressure of the transformer, which is of the ordinary oil-cooled pattern, with a capacity of three kw., is varied by means of an inductance, *A*, in the primary circuit, as indicated in the diagram of connections given in Fig. 1. Besides driving the motor-generator set, the battery is used for lighting the building. The capacity of the battery, which consists of 52 cells of the D.P. Accumulator Co.'s pattern in glass boxes, is 180 ampere-hours on a nine-hour discharge rate. As shown in the diagram, the signalling is done in the generator circuit by means of an ordinary Morse manipulating key, *B*, which controls a special form of magnetic key, *C*. The function of this latter key is to prevent the circuit from being opened at any time except when the alternating-current is passing through its zero value; injurious sparking at the contacts of the manipulating key is thus prevented. The secondary of the main transformer, *D*, is connected through two iron core choking coils, *E*, and two air choking coils, to the battery of condensers, *F*; and the oscillatory circuit, consisting of the spark gap, *G*, high-frequency tuning inductance, *H*, and the primary coil of the high-frequency oscillation transformer, *K*, is connected across the condenser as shown. The iron core choking coils *E* prevent any high-frequency oscillations from reaching the main transformer *D*. Fig. 2 shows the construction of the spark gap, which is of the standard Marconi pattern; the one illustrated, however, is for a 1·5-kw. plant, and is rather smaller than that installed in the present station. The mushroom-shaped electrodes are of iron, and are mounted on ebonite pillars. In order to vary the gap, which can be anything between 2 and 8 mm., the electrodes are screwed to the left or right as desired. The normal working value of the gap is 5 mm. As shown in the figure, the spark-gap is entirely boxed in to deaden the noise of the discharge. Fixed to the pillars are two guard

D

Digitized by Google

points, which are set to limit the pressure across the gap to a certain amount, in order to protect the condensers.

There are four condenser tanks similar in design to that illustrated in Fig. 3, and consisting of a number of thin iron plates separated by glass plates, and immersed in oil. It will be noticed that the condenser illustrated has a zinc-lined box with a further internal lining of cork. When the condensers are connected in two groups (of two in parallel) in series, the total capacity is 0·07 microfarads, and the corresponding inductance in the oscillating circuit is 2·3 microhenries. The primary of the high-frequency oscillation transformer consists of one turn only, and the secondary of ten turns. Adjustable couplings have been provided in the oscillation transformers in this station, and these permit of a loose coupling being made between the oscillating circuits; in consequence a sharper and more defined wave can be obtained, with improved tuning capabilities. When it is desired to operate with a 600 metre wave, one terminal of the secondary of the oscillation transformer is connected to the aerial, and the other is earthed. As shown in the diagram of Fig. 1, however, a further oscillating circuit can be connected in cascade with the first one for the purpose of working with a different wave-length. In that case the secondary of the oscillating transformer K is connected across a second battery of condensers L, in circuit with which is a second spark-gap M, a tuning inductance, and the primary of a second oscillation transformer N. The secondary of the latter is then connected to the aerial and to earth, as shown in the diagram. In neither case is the aerial directly earthed through the secondary, as a small "arrester" spark-gap P is interposed between the latter and the earth connection. The function of this will be explained later, but it may be mentioned here that, when transmitting, this gap is practically non-existent, as a discharge to earth occurs every time the aerial is charged.

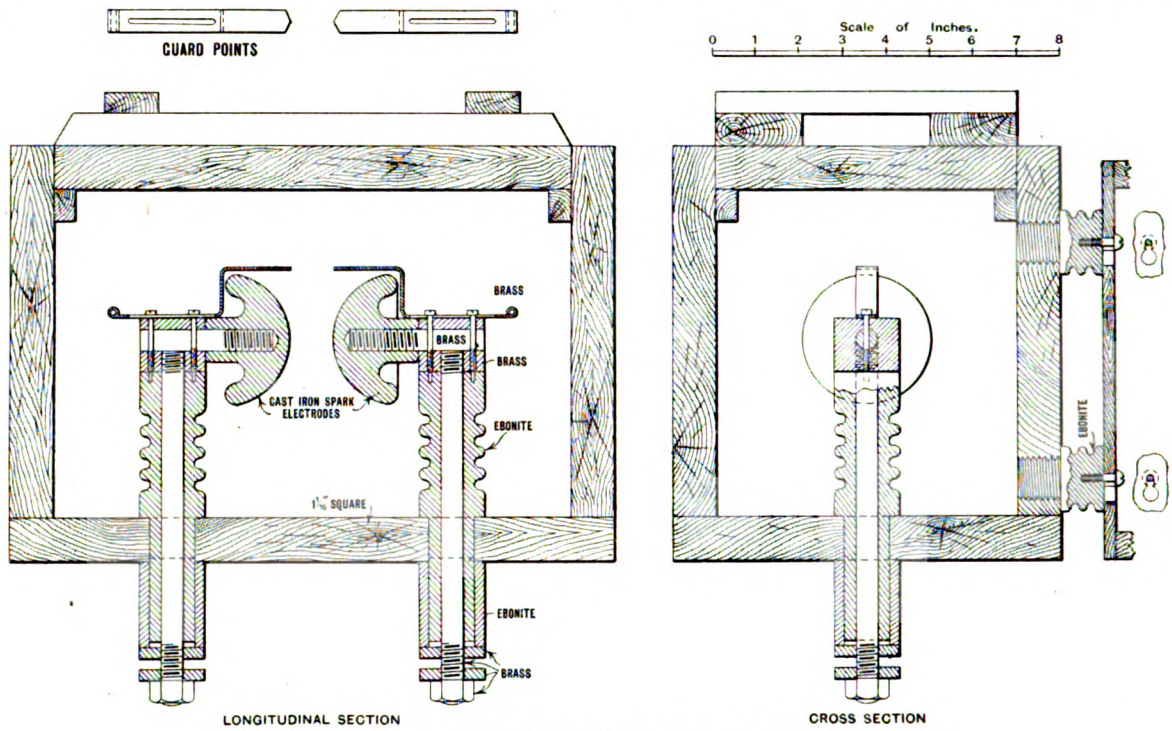

Fig. 2.—Sections of Enclosed Spark Gap.

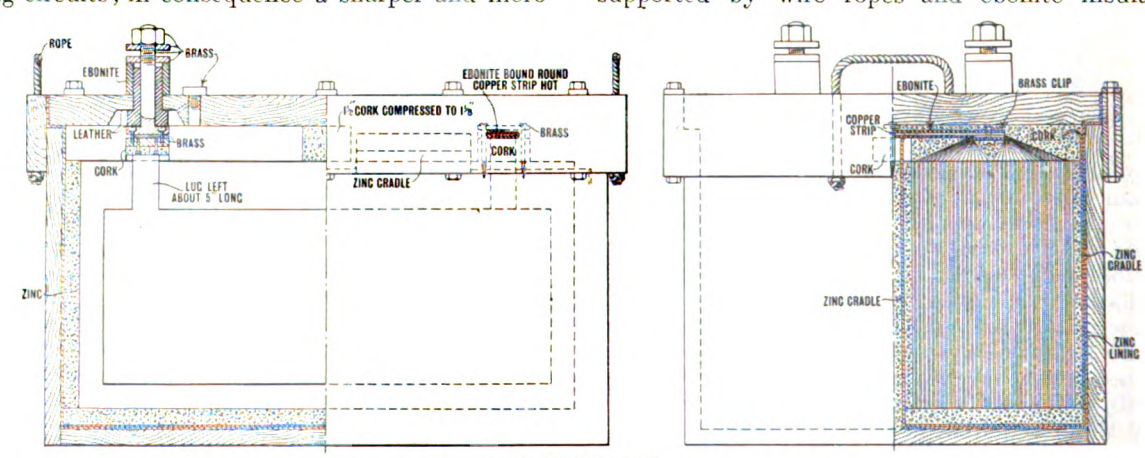
The arrangement of the mast and aerial is shown by the sketch of Fig. 4. Four small 30-ft. poles surround the main mast, which is 160 ft. high, and the aerial conductors, which consist of stranded copper-wire, are supported by wire ropes and ebonite insulators, as shown. The aerial is thus of the umbrella type, with four radiating arms and two central conductors, which terminate at the instrument house. To protect the instruments from lightning, a "thunderstorm switch" is provided. This consists of a metal ring connected to the aerial, which slides on a long ebonite rod; during a thunderstorm this ring is pulled along the rod by means of a cord, extending into the instrument room,



(Scale ¼th full size.)

Fig. 3.—Sections showing Construction of Condensers.

Digitized by Google

until it touches an earthed metal flange at the extreme end of the rod. The aerial is led into the instrument room through a Bradfield insulator. To provide an efficient earth connection, thirty galvanised iron plates have been buried edgewise in a circle round the station, and these are connected by sixty wires to the earth conductor in the instrument room.

The receiving apparatus is of the usual Marconi pattern, and comprises a magnetic receiver B, and a separate filing coherer receiving set S, which is connected direct to the aerial, as shown in Fig. 1, and left in circuit when the operator is not using the magnetic receiver, so that an audible bell call can be given. When transmitting, the coherer receiving set is automatically disconnected from the aerial by the switch X. The Marconi form of magnetic receiver consists of a moving band of iron wires, which passes through two concentric coils, one of which is connected to a telephone receiver, and the other between the aerial and earth. The portion of the band in the coils at any instant is under the influence of a permanent magnet, and variations in the magnetism of the band, produced by the aerial current, cause corresponding sounds in the telephone receiver. This type of receiver, in conjunction with many others, was described in an article on receivers in ELECTRICAL ENGINEERING, Vol. I., page 241. An important feature in this installation is the provision of means whereby the operator can be interrupted while dispatching a message. This is done as

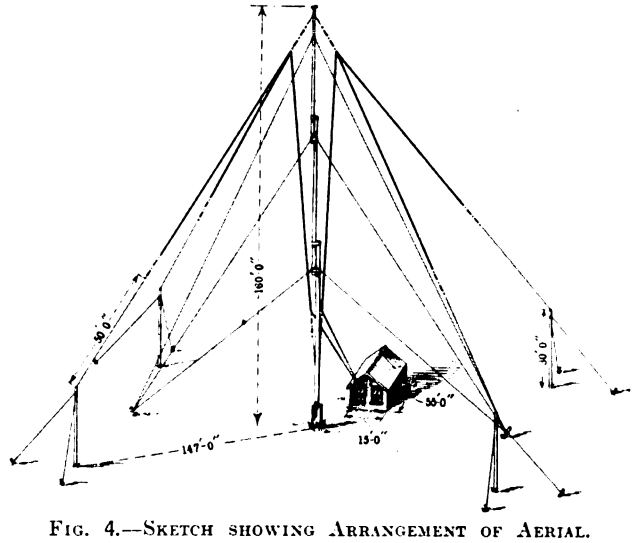


FIG. 4.—SKETCH SHOWING ARRANGEMENT OF AERIAL.

follows:—Both the magnetic receiving instrument and the transmitting instruments are always connected to the aerial, but the telephone receiver of the former is automatically short-circuited by means of the contacts shown in the diagram of connections at T, when the manipulating key B, in the transmitting circuit, is depressed. It would not of course be practical to have the aerial coil of the magnetic receiver in series with the aerial, either directly or indirectly through a transformer, when transmitting, but this difficulty has been got over by placing the previously mentioned "arrester" spark-gap P in the aerial circuit, and connecting the magnetic receiver R across this gap through the "tuners" V or Y. This gap, which offers little or no resistance to the current surges during transmission, compels the small induced receiving currents to pass through the receiving instruments. It is evident that were the gap not present, the receiving apparatus would be short-circuited. As the operator always has the telephone at his ear, signals received during the intervals of transmission can be heard.

For tuning purposes, the receiving apparatus includes two units of the latest pattern of the "Marconi" multiple tuner V and Y, the function of which is to tune the receiver or render it immune to interference from other stations. It may also be used for measuring the lengths of the transmitted and received waves, and under certain conditions for estimating the distance of a known station. The V unit is for large-wave lengths, and the Y unit for short wave-lengths. The instrument contains three separate circuits called the aerial circuit, the intermediate circuit, and the detector circuit. The first consists of a tuning inductance in series with a tuning condenser and an inducing inductance, the latter in magnetic relation with an inductance in the intermediate circuit. In the latter circuit there are two inductances in magnetic relation with the other two circuits respectively, and a tuning condenser in parallel with the inductances. The third circuit consists of an inductance in series with a tuning condenser and the detector or receiver. The two inductances in the aerial circuit and the three tuning condensers are all adjustable, and by means of these adjustments all the three circuits are tuned to the received wave-lengths. The oscillations in the aerial circuit then induce oscillations in the intermediate circuit, which in turn induce oscillations in the detector circuit. In addition, the coils in magnetic relation may be moved relatively to one another, so that the couplings between the three circuits may be varied. The instrument is also fitted with a micrometer spark-gap and a shunt inductance of the order of 80,000 microhenries, connected between the aerial and earth terminals to prevent the accumulation of an electrostatic charge in the aerial. A change-over switch by means of which the tuned circuits can be cut out, and the receiver instantly rendered sensitive to a wide range of wave lengths, is also provided. One terminal of the aerial circuit is connected to earth, and the other is connected to the top of the "arrester" spark-gap, so that connection is made through the secondary of the oscillation transformer N to the aerial, as shown in the diagram of Fig. 1. When receiving with this instrument, first the inductances and then the condensers are adjusted until the strongest signals are obtained. The wave-length can be read off on one of the dials of the instrument. When the apparatus is left without an attendant, the aerial is connected direct to the filing coherer set S by the switch X; and this set, in conjunction with a relay and a Morse ink receiver, records all the signals received.

The station is in direct telegraphic communication with Exeter, and messages received from ships at sea will be transmitted inland via that city. In order that messages from Exeter may be received by the operator in the transmitting room, he has a "head-sounder," by means of which he is enabled to receive the messages in spite of the noise. It is also proposed to install a system of relays and lamps in order to render the signals visible. It is officially stated that the charge for communication with ships will be, in most cases, 8d. per word. This charge is made up of 3½d. per word for the coast station, 4d. per word for the station on board the ship, and the ordinary telegraphic rate of ½d. per word for the transmission by wire to and from the station. Great precautions had to be taken to prevent the magnetic receiver from being affected by the telegraph circuits. The speed of signalling which has been attained with the system used in this station is that usual with key operation—namely, about 30 words per minute. A large 10-inch spark-coil is included in the equipment of the station, and this could be supplied direct from the battery, and used instead of the ordinary generating plant, in case of a breakdown of the latter. Attention may also be drawn to the so-called "guard-lamps" Z, which are ordinary straight carbon filament lamps connected across the machines, to prevent the high-frequency oscillations reaching the armatures. The whole of the wireless apparatus, the mast, and the aerial were supplied by Marconi's Wireless Telegraph Co., Ltd., and the generating plant was installed by the Westminster Engineering Co.

In conclusion, we wish to express our thanks to Mr. J. E. Taylor, Assistant Superintending Engineer of

Digitized by Google

the Metropolitan Central District, under whose supervision the work was completed, and to Mr. J. Robb, of the Engineer-in-Chief's department, for putting at our disposal the drawings from which the illustrations in this article have been prepared, and for giving our representative particulars of the work. We also wish to acknowledge the assistance of the Marconi Co., who accorded us full information respecting the equipment supplied by them.

At the opening of the station on Friday last, the Postmaster-General was supported by Sir H. Babington Smith, Secretary of the Post Office, and several Post Office officials of the Western District. In declaring the station open, Mr. Buxton referred in a short speech to the previous work of the Post Office in the domain of wireless telegraphy, but pointed out that the present station was the first one which would be used by the Post Office for commercial purposes, under the regulations of the Radio-Telegraphic Convention. The cost of the station, he said, was about £2,000, whereas the cost of a submarine cable was between £200 and £400 a knot, so that communication could be effected much cheaper by wireless telegraphy than by cable. He then referred to the good work done at the International Convention by Sir H. Babington Smith on behalf of Great Britain, and expressed the view that the results of the Conference were very favourable to British interests.

THE FIRST REVOCATION OF PATENTS UNDER THE PATENTS ACT OF 1907

ON Wednesday last week, the Comptroller-General of Patents issued an Order that two patents covering a manufacturing process which is being carried on exclusively outside the United Kingdom, are revoked. This is the first decision under the revocation clause of the Patents and Designs Act, 1907, which provides that after August 28th, 1908, any person may apply for the revocation of a patent not less than four years old, on the ground that the patented article or process is manufactured or carried on exclusively or mainly outside the United Kingdom. The decision is subject to appeal to the High Court, and of course until the appeal has been heard the case cannot be regarded as establishing a certain precedent, but in the meantime it is interesting to note the point of view taken by the Comptroller, for he is vested in wide discretionary powers under the Act. He is authorised to refuse to revoke the patent if satisfactory reasons are given for the patentee having neglected to work his patent in this country.

The subject of the patent hardly comes into question at all, except in so far as it may have a bearing on the reasons why the patented article has not been manufactured here. In this case, the patents are not for any electrical apparatus, but relate to a process for making thin imitation stone slabs or tiles, and it appears that there has been a demand for these particular slabs in this country, as one-sixth of the total sales from the Belgian factory, where the process is carried on, are placed on the British market. After examining the evidence, the Comptroller came to the conclusion that there is no inherent reason why the process should not be carried on commercially in this country. It was admitted by the company owning the patents that the articles in question are produced in Germany at a very cheap rate, and on a very extensive scale, and there is also a factory in France. There is little, if any, difference in the prices at home and abroad of the materials used or in the facilities for obtaining them, and the only other reason which has been alleged why the process can be more profitably carried on in Belgium, Germany, and France, than in the United Kingdom, is that the wages of the workpeople in those countries, who in the carrying out of the patented process now under consideration for the most part are unskilled labourers, are lower than in England. If this reason is an insuperable bar to the introduction of the industry to this country, the Comptroller remarks, it is very difficult to understand how many industries which are carried on successfully in the United Kingdom continue to be so carried on.

The next point dealt with by the Comptroller was the steps which the owners of the patents asserted that they had taken to dispose of their rights in this country. During last August, it will be remembered, large numbers of advertisements were inserted in the technical papers for buyers or licensees of patents, which were at the time worked only abroad. In the large majority of cases the patents were advertised by title only, and it would certainly appear to the average mind that the fact of no reply having been received to an advertisement of this nature could hardly constitute an adequate reason for the non-working of the patent in this country. In this particular case, a few letters or circulars were also sent to British manufacturers of bricks and tiles, offering to sell the patents or to grant a licence under them. The Comptroller's views with regard to such advertisements and offers are set forth very clearly in his decision. He says that he cannot regard the fact that no answers were received by the patentees to their advertisements and offers as a satisfactory reason for not manufacturing in this country. "In the first place, they were not inserted or made until very near the expiration of the year of grace which had been allowed the patentees by the Act; and, even if they had attracted the attention of persons who might otherwise have been willing to work the process, the fact that only a month of the year of grace remained unexpired would naturally make manufacturers less willing than they otherwise might have been to enter into arrangements with the patentees. For anyone acquiring the patent rights would be in no better position to defend the patents against applications for revocation than that which the patentees themselves from whom he bought them possessed. It seems to me impossible to hold that a patentee can relieve himself from the duty of manufacturing in this country by the mere insertion at any time of a few advertisements, and the sending round to manufacturers of a few circulars to which no replies are received. The advertisements and offers in this case were, I may say, of the vaguest description; they gave no intimation of the terms on which the owners of the patents were prepared to treat, beyond the statement that such terms would be reasonable."

In answer to the suggestion that patentees who had taken out their patents before the passing of the Act should be treated with greater leniency than those who have since taken out patents, the Comptroller points out that a year of grace was allowed by the Act itself, and that nothing in the Act would justify him in lengthening this period. The two patents in question were taken out in 1900, but the same would apply to any patents more than four years old.

Another important conclusion is that the motives of the applicant for the revocation are apparently quite irrelevant to the issue. In this case it had been suggested that the applicant was disentitled to succeed in his applications, because he had no intention of manufacturing the patented article himself, his only object being to obtain liberty to import from France or Germany. "I have often heard it suggested," the Comptroller says, "that the section is unduly hard on patentees because it enables any person to apply for revocation even though he, in doing so, may be a mere

Digitized by Google

busybody concerning himself in a matter in which he has no personal interest whatever. This is the first time I have heard it suggested that an applicant is disentitled to obtain an order for revocation because he is personally interested in the revocation."

This point is somewhat elaborated. The Comptroller says:—"It has further been contended by the counsel for the patentees that the object of the section being merely to bring about the establishment of new industries in this country, a patent may not be revoked under it unless it can be shown that the revocation will lead to the establishment of such new industries. In the present instance, if the patents are revoked, it seems to me impossible to say that a new industry will not be established in this country where no royalties will be payable in respect of the carrying on of the process; but even if no such industry is started here, their revocation will undoubtedly have one beneficial result, for it will free the trade in the patented article and enable French and German manufacturers to import it freely into this country, the effect of which may very possibly be to reduce its price and, whilst in no way preventing its importation from the Belgian factory, give purchasers an opportunity of selecting for themselves between the articles manufactured there and at other foreign factories. . . . I have always regarded the object of the section as being to put a check on the practice, which was alleged to prevail very extensively, of taking out and maintaining patents in this country, not with any intention of working them here, but with the object of preventing the patented articles from being manufactured here, and from being imported by any other parties than the patentees."

The decision concludes as follows:—"Having come to the conclusion that the patents should be revoked, the question arises whether I should revoke them forthwith, or, as I am authorised to do under subsection 2 (*b*) of the section, after a reasonable interval to be specified in the Order. I cannot think that any advantage would be gained by allowing such an interval. The only step alleged to have been taken by the patentees with a view to compliance with the requirements of the section, before the application for revocation was made, was the issue of the vague and futile advertisements and offers above referred to during the last month of the year of grace allowed by the Act. If I were to allow any further opportunity to the patentees to comply with the requirements of the law I should be establishing a precedent, the practical result of which would be to encourage patentees to defer compliance with the requirements of the section until applications are made to revoke their patents. Moreover, if it be true as has been urged on behalf of the patentees, that they cannot afford to work the patented process in this country, and that, if they do, they must raise the price to the consumer, it will be no real kindness either to them or to the public to delay the revocation of the patents. If the patents are revoked forthwith, as it appears to me they should be, it is by no means improbable that someone else may undertake the working of the patented process in this country; but, whether or not such a person can be found, the trade will be freed, and liberty given to import the patented article, not only from Belgium, but also from France and Germany, and any other country in which it may be produced."

As an indication of the cost of procedure under this section of the Act, we may add that, although in this case there were comparatively few witnesses on either side, the Comptroller decided that the patentees should pay the applicant 45 guineas in respect of the costs of his applications.

COMMERCIAL ELECTRIC HEATING

IN his Paper, which was down for reading before the Institution of Electrical Engineers last Thursday, but which, owing to considerations of time, had to be taken as read, Mr. J. Roberts, of Durban, referred first to the effect of a universal demand for current for heating and cooking purposes, and said that many engineers who had been driven to increase their distribution pressures to 2×230 volts did not care to contemplate what would be the result even if the maximum demand of the average small residence went up from, say, 3 amperes to 20 amperes. This, he thought, constituted a strong plea for higher distributing pressures in conjunction with reducing transformers, and in connection with the questions of alternating *versus* continuous current, which this opened up, he briefly recapitulated the advantages of two-phase generation and distribution, and suggested the adoption of 800 volts as a distributing pressure, with a simple form of distributing mains consisting of single conductors with waterproof insulation laid on porcelain insulators in water-tight iron troughs.

The author strongly condemned the pressure of 230 volts as quite unsuitable for use on consumers' premises, especially with some forms of cooking apparatus on the market. "In order to obtain the full benefits of the safety and convenience of electricity," he said, "we must get back to low pressures for both heating and lighting, for the mischievous raising of pressures has been the deliberate means of discounting these two important advantages. I need not refer to the superiority of low-pressure lamps. The metallic filament lamp emphasises it. I sincerely hope, in the best interests of the industry, that a 16-c.p. 230-volt lamp will never be practicable, so that sheer necessity will force us to give a more rational pressure to the consumer."

The Paper then passed on to the consideration of cooking apparatus, and submitted that for such purposes, also, low pressures were advantageous. High-pressure cooking appliances were, from their very nature, expensive and likely to get out of order, and that the chief advantages of electricity—*safety* and *convenience*—could only be fully realised by the use of low pressures. Another essential for the realisation of his ideal was that ordinary cooking work should be done with utensils without flexible cords. It follows that utensils must be heated by placing them in contact with hot plates, and a proper corollary follows that hot plates must be designed to prevent radiation of heat in any direction other than where it is wanted.

It was also highly desirable that utensils should be double walled to economise heat to the last degree.

Figs. 1 and 2 show in section and elevation a form of stove

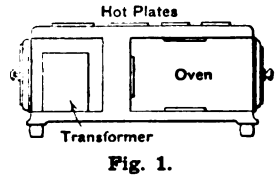

Fig. 1.
STOVE IN SECTION

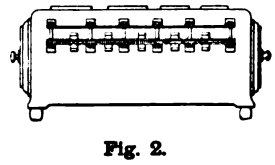

Fig. 2.
ELEVATION OF STOVE.

proposed by the author to meet these conditions. The outer case is made of sheet-iron or steel, the top is fitted for four hot plates, two large and two small. The body is taken up on the right-hand side by the oven, a compartment on the left holds the reducing transformer, fed by the 800-volt distribution mains, and wound so that 50 volts can be taken out for the lighting circuit. Three other taps from the secondary are brought to copper bars running across the front of the stove, so that 7, 12½, or 20 volts can be applied to the elements. The stove is vacuum insulated, and the elements are securely fixed to the under side of the hot plates and to the lining of the oven. Fig. 3 shows in detail the construction of the hot plate. The hot plate as commonly made to-day is usually wrongly designed in that there is no proper insulation of the heating element underneath the plate, so that draughts carry off heat and reduce its temperature, and there is no provision to shield the imperfect surfaces of contact between plate and utensil, so that convection currents of air circulate across them and reduce efficiency. The type of element suggested for use on 20 volts is shown in Fig. 4. It is made of a circular sheet of metal of proper thickness cut spirally, sufficient metal being removed at the cuts so that no insulation is wanted between the turns so

Digitized by Google

formed. Fig. 3 of the assembled hot plate in section shows that the element is secured between the under side of the hot plate and a strongly ribbed casting in order to hold it in as close contact as possible with thin sheets of mica as insulation. Rivets clamp everything together thoroughly. The assembled

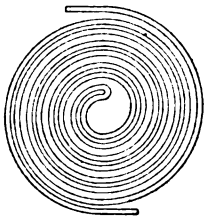

Fig. 4.

Fig. 3.

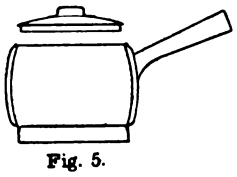

Fig. 5.

plate is fixed to the top of the stove through a ring of asbestos to prevent conduction as far as possible laterally. Fig. 5 shows a pot suitable for use with the plate. The sides of the pot project below the bottom in order to shield it from draughts of air blowing between it and the plate, and the whole is double lined, as also the lid.

One end of the winding of each element is permanently connected to the end of the transformer secondary, and the other to a contact so arranged that a plug can be made to connect either of the three copper bars running across the front of the stove.

Figs. 6 and 7 show a side and a front elevation of the three

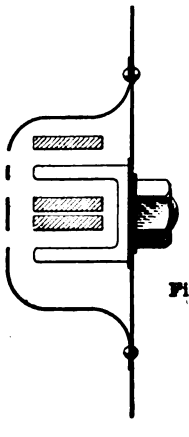

Fig. 6.

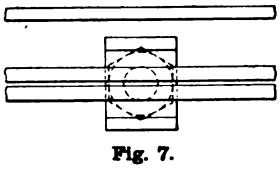

Fig. 7.

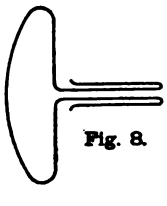

Fig. 8.

bars on the stove with the contacts connected to the heating element. Fig. 8 shows the form of plug. No insulation is used on the handle. The plug can be inserted so as to connect to any of the bars, and the handle is so shaped that two plugs cannot be inadvertently used on the same element and so short circuit a transformer winding. The transformer will be of efficient design and will not dissipate much energy. What is lost will, however, help to keep the stove warm, and will not be wasted.

The Paper concluded with a few remarks on systems of charging suitable for mixed power and lighting loads. The author was in favour of the "Norwich" system, which involves a fixed charge depending on the rateable value of the premises, plus a small price per unit used.

The Mile End Road Surface Contact Tramway.—In a report this week, the Highways Committee of the London County Council states that a question having been raised and varying statements having been made as to incidents which have occurred during the experimental working of the G.B. system in the Mile End Road, they have decided to make the following report to the Council of information given by the Council's officers as to the number of live studs, accidents, and claims incidental to the working of that system of electric traction on the Aldgate to Bow tramways. There were 927 occasions recorded on which alarm indicators operated on cars, showing that studs remained alive immediately after the cars left the studs; 728 of these cleared themselves; 185 cleared after being hammered; 7 studs would not clear and remained alive. The total number of cases in which it had been reported that accidents occurred, or were alleged to have occurred, is seven. In three cases claims were received and dealt with by Mr. Godfray, the solicitor acting for the Council in connection with accidents on its northern system of tramways, and under the general authority given to him to settle claims during the summer recess up to £50, or between meetings of the Committee up to £25, Mr. Godfray settled these claims by payments amounting in all to £60 4s.

THE PHYSICAL SOCIETY'S EXHIBITION

THE annual exhibition of electrical, optical, and other physical apparatus was held last Friday by the Physical Society of London at the Royal College of Science, South Kensington, when about twenty manufacturers of instruments, experimental and demonstration apparatus displayed their latest productions. Telegraph apparatus was represented on the stand of the India Rubber, Gutta Percha & Telegraph Works Co., Ltd., who showed examples of the Raymond-Barker two-tone transmitter, by means of which in conjunction with the Gott fault-searcher coil inductive signalling has been carried on over a distance of 60 miles between a cable-ship and a submarine cable station during the making of the final joint and splice of a cable repair. On the same stand were shown the Appleyard conductormeter and conductivity bridge, and several patterns of the well-known Silvertown portable testing sets.

Among the displays of instruments may be mentioned that of Messrs. Nalder Brothers & Thompson, Ltd., which included testing sets and a new temperature measuring apparatus known as the telethermometer. It consists of a moving-coil ohmmeter, and is worked on the bridge principle. A coil of wire having a high temperature-coefficient is mounted in the metal case and corresponds to the thermometer; leads are brought from this to the indicating instrument. The voltmeter is supplied from a small hand generator, or alternatively from the lighting mains.

One of the most interesting instruments on the stand of Messrs. Everett, Edgecumbe & Co., Ltd., was a high-tension electrostatic voltmeter of the Jena pattern, ranging up to 60,000 volts. The Trotter universal photometer was also shown (see Electrical Engineering, Vol. I., page 849), and a very representative collection of indicating and recording instruments. Another good display of instruments was made by Messrs. Elliott Bros. Among these, in addition to the galvanometers and other laboratory instruments, was shown a centre zero milliammeter arranged with appropriate connections and push buttons for use as a leakage indicator. The portable standard wattmeter shown was also worth examination. In this instrument, which is of the dynamometer pattern, the moving coil swings outside a ball-shaped fixed coil. Other apparatus shown by this firm included the Harrison Universal Photometer. Another firm showing photometer apparatus was Messrs. Alexander Wright & Co., who exhibited the Simmance-Abady patterns of laboratory and street photometers, already described in our columns in connection with the Manchester Exhibition (see Electrical Engineering, October 29th, supplement, page 40).

A large display of instruments was made by Messrs. Siemens Brothers & Co., Ltd., including continuous- and alternating-current ammeters, voltmeters, &c., for testing purposes, combination instruments for a number of ranges, and the conveniently arranged Siemens's "Universal Galvanometer," fitted with a circular slide wire so that a great variety of different kinds of measurements can be made with it. Several patterns of galvanometer were also shown, and a useful form of induction bridge for determining induction constants and energy losses in alternating-current apparatus. Another piece of alternating-current testing apparatus shown was a small high-frequency generator for about 1,000 cycles per second. Other exhibits on the same stand were a magnetic testing outfit and a collapsible photometer. A complete Roentgen-ray equipment was also shown.

Mr. Irwin's hot-wire oscillograph, which he described in a Paper read before the Institution of Electrical Engineers (Electrical Engineering, Vol. I., page 970), was demonstrated, together with other apparatus by Mr. R. W. Paul. Some of Dr. C. V. Drysdale's instruments, including his standard wattmeter and phase-shifting transformer, were exhibited by Messrs. Snell & Tinsley, who also showed some telegraph apparatus.

Laboratory electric furnaces were shown by J. J. Griffin & Son and A. Gallenkamp & Co., and a large display of physical apparatus, among which may be mentioned standard Western cells, constructed according to the suggestions of the International Conference on Electrical Units and Standards, was given by the Cambridge Scientific Instrument Co. Mr. L. H. Walter's tantalum-wave detector was shown by Messrs. A. C. Cossar, Ltd., and among the exhibits of Messrs. Newton & Co. was a pair of lamps for demonstrating the properties of Mr. W. Duddell's musical arcs. Other exhibitors included Messrs. Casella & Co., Messrs. J. H. Dallmeyer, Ltd., Messrs. A. Hilger, Ltd., Messrs. Swift & Sons, and Messrs. Carl Zeiss.

Royal Institution Lecture Arrangements.—The following lectures are among those arranged for at the Royal Institution before Easter, 1909:—Friday Evening Discourses: February 12th, "The Electrical Properties of Flame," by Prof. H. A. Wilson, F.R.S.; March 12th, "Modern Submarine Telegraphy," by S. G. Brown; April 2nd, "Electrical Striations," by Prof. Sir J. J. Thomson, F.R.S. Among the afternoon lectures will be a series of six by Sir J. J. Thomson, on February 27th, March 6th, 13th, 20th, 27th, and April 3rd, the subject being "Properties of Matter." The lecture hour on Tuesday and Thursdays during the 1909 season has been changed to three o'clock.

SYSTEMS OF RECORDS FOR MAINS

THE Paper on plans and records for electrical distribution systems, read last night by Mr. J. W. Beauchamp at the meeting of the Leeds Local Section of the Institution of Electrical Engineers, emphasised the importance of accurate records of the positions of mains in a complicated network, and, reviewing some of the requirements which should be possessed by a system of records, proceeded to describe the methods adopted in Sheffield.

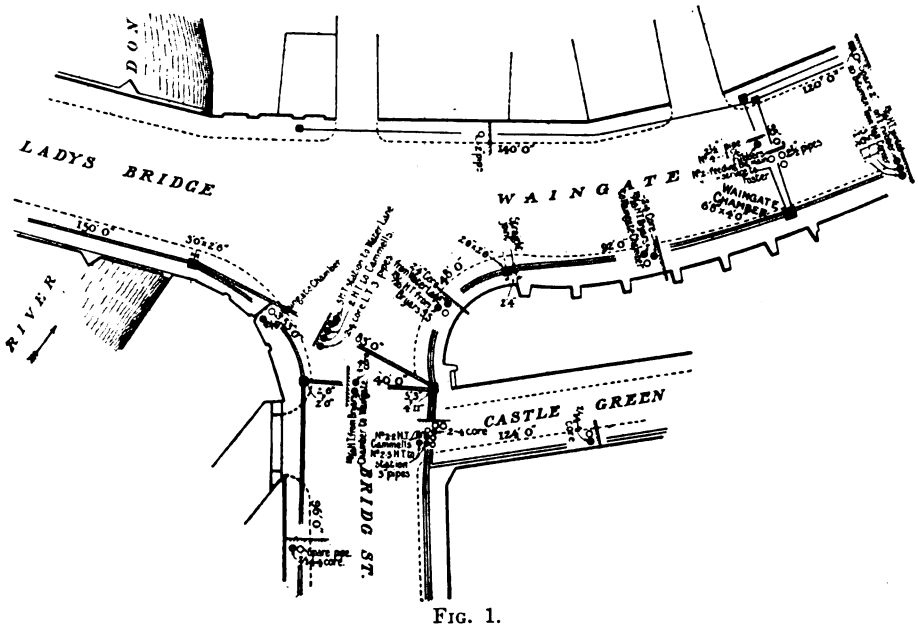

FIG. 1.

The principal features of the method as carried out at present are as follows:—

A key map of the city divided into squares and marked with reference numbers to a set of Ordnance sheets (scale 1 in 500 or 41·66 ft. to 1 in.) to cover the area included in the city boundaries. The area enclosed by lines joining up the extremities of existing mains is about 8 square miles, which represents the size of the district over which supply is at present or can generally be given without making any great extensions. On these Ordnance Sheets the positions occupied by pipes and cables are shown as follows:—All the pipes and cables on either side of a road are represented by a single line on that side of the road on the map, high-tension cables being indicated by a red line, low-tension cables by green, spare pipes by yellow (draw-boxes by a square (black), sub-stations by a square (green), switching pillars and boxes by a circle (green), service connections by a tee-line off the cable, to scale with regard to position along the building line. Densely cabled areas are re-drawn to a larger scale, permitting of more detail and sectional insets are shown where needed (Fig. 1).

On the plans draw-boxes, disconnecting pillars, and sub-stations of every kind are marked with a number referring to lists and cards kept in an index cabinet. These cards are specially ruled, and when filled in each one shows details of size, position, and contents of any two adjacent draw-boxes, and a cross-section of all ducts and cables between them, this information being amplified by means of detail sketches on the back of the card where the complexity of the work calls for it. Numbers referring to the Ordnance Sheets on which the courses of the detailed cables appear are also given on the card.

When extensions are proposed, full particulars of pipes, cables, and courses to be followed are entered on a printed form. This constitutes an instruction to the draughtsman who makes the tracing from the Ordnance Sheet or Sheets of the locality where this work is to be carried out, and the proposed cables are shown upon it in a different colour from that used to indicate existing works. From this a card is entered up and the course of the cables laid is marked on the Ordnance Sheet in the proper colours, where also the draw-box positions are marked with the consecutive numbers which give reference to the street card, which is then filed alphabetically under the name of the street.

Service connections are similarly dealt with, but the detail record is allowed to remain in the ruled sketch-books, which are preserved for reference. In addition to these records the whole of the high-tension cable system and transforming points are shown on a skeleton map.

Some figures concerning the size of the system at Sheffield and cost of record-keeping are given in the Paper. The network joins up two generating stations about 1¾ miles apart, and is complete in the central area. Its limits extend some four miles from the old station in the centre of the city, and in the residential portion it is in a fairly complete condition. In the eastern industrial districts there is also an extensive and heavy mains system, although apparently great increases will be called for before the demand in this direction is fully met; consumers' connections aggregate about 16,000 kw. The work of recording all mains extensions, services, and alterations is carried out by one draughtsman and two assistants occupying only a part of their time, about equal to the continuous labour of one man and a junior, to which must be added the cost of supervision by the chief draughtsman, and a small allowance for the attention of the mains engineers. For labour, say £200 per annum, the equipment consists of a set of maps and cards and filing cabinets—approximate value, £60; in addition, a considerable amount of drawing-office material is used.

From experience gained of working with the present method several useful improvements of this system of records have suggested themselves, and are being considered.

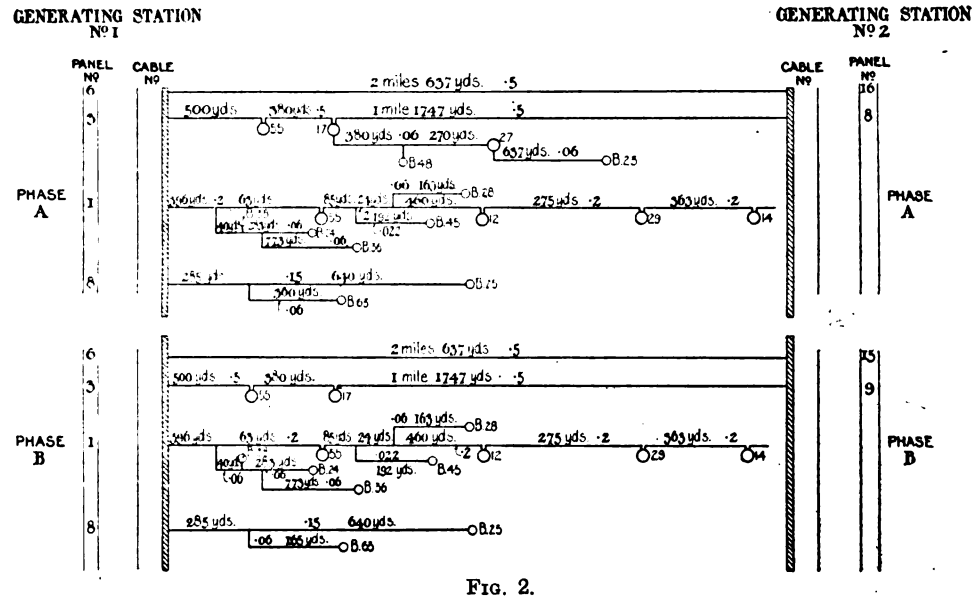

FIG. 2.

In the complete system proposed below, the object has been to provide for every needful detail of cables and their position, and in addition to give particulars of connections, loading, and balancing in an accessible form.

The following are the essentials of the system:—

I.—Key map of the area giving reference to the Ordnance Sheets.

Digitized by Google

II.—Set of Ordnance Sheets on which the course of (*a*) High- and low-tension cables and spare ducts are shown with single lines of different colours; (*b*) Sub-stations, disconnecting pillars, and boxes, by reference letters and numbers; (*c*) Street draw-boxes or selected points in thoroughfares by numbers referring to the card on which details of the works at these points are shown.

III.—A map of the whole area on the largest practicable scale with high-tension feeders and low-tension distributors shown by a suitably coloured line, and all high-tension terminal points, sub-stations, or transformer boxes, public or private, indicated by their reference number.

IV.—A diagram of all high-tension cables showing (*a*) The generating station and switch panel from which each originates; (*b*) all tee, in-and-out, and terminal points with reference numbers; (*c*) sizes and lengths of cables.

V.—A list of reference numbers and symbols for (*a*) All high-tension sub-stations, pillars, boxes, and terminal points; (*b*) all low-tension disconnecting pillars and boxes.

VI.—A set of cards for particulars concerning all sub-stations.

VII.—A set of street cards presenting diagrammatic plans of the thoroughfares and sections of all the mains at points as near together and numerous as is necessary to present a complete record of the network, also particulars of consumers' connections filled into spaces which are provided for *all* premises along the course of the mains.

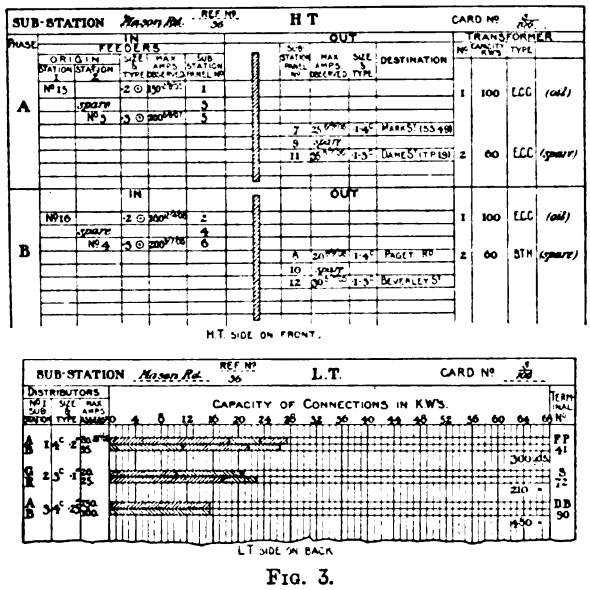

FIG. 3.

VIII.—A file of the extension and service note-books used by the draughtsmen to record daily work on the mains.

The key map should be divided into as many squares as there are Ordnance Sheets in the set, each square bearing the number of the section sheet, which is an enlarged copy of it. The set of Ordnance Sheets should be kept flat in suitable drawers and arranged in order of their reference numbers. These sheets should be kept up to date in all details, by re-drawing from time to time any portions where roads and building lines are altered, and the position of all cables should be shown as nearly as possible to scale by a line on each side of, or crossing the roads, a system of colours being adopted to distinguish between feeders and distributors and empty pipes. The position of service connections may also be shown upon them to scale with regard to street corners or salient points on adjacent buildings. Sub-stations and distributing boxes of all classes are marked with letters and numbers, referring to the cards which give details of them. Numerous points are also indicated by simple numbers which refer to the alphabetically indexed cards in which the whole of the streets are shown in short portions with cross-sections and full details of the work at every point. Beyond this no details are given on the Ordnance Sheets, which really act as a large scale key map to the rest of the record equipment, and provide exact particulars for every part of the area for use in planning and estimating for new work.

The general map of the area to a large scale, has all mains shown in one or two colours, and the numbers of all feeder or high-tension terminals marked on. This map may appear to be a scanty repetition of the information given on the Ordnance Sheets, but in practice it should be found useful to give a bird's-eye view of the feeding system, and a quick reference to its principal points, while keeping in view the form and growth of the network and relative distances.

The diagram of the whole of the high-tension or feeder cables from their origin at the station switchboard is shown in Fig. 2. With reference to the details of every tee, in-and-out, and terminal point, with length and sizes, further vertical columns may also be used to record maximum amperes observed on each feeder, and reference to periodical insulation tests.

As an alternative to large sheets for this diagram, long, narrow strips of card might be used, one for each panel on the switchboard, with space for reasonable increase being made in the number of tees and branches off the cable. This would render it easy to re-draw any particular feeder in the event of great extension or alteration. The numerical list of important points and terminals divided into classes is arranged alphabetically as well as consecutively, each number preceded by a distinguishing letter. The sub-station cards are ruled on each side, the front (Fig. 3) showing every high-tension cable entering and leaving the sub-station, with particulars of: (*a*) Origin or destination; (*b*) panel number on the sub-station switchboard; (*c*) size and type of cable; (*d*) Maximum load observed; (*e*) transformers, number and type. The back of the card (Fig. 3) shows similar particulars of each low-tension distributor leaving the sub-station, and in addition a graphic representation of the capacity and state of balance of consumers' connections upon it. A further vertical column might with advantage be added to the main high-tension diagram and the high- and low-tension sides of the sub-station cards, in which particulars of the fuses or circuit-breaker settings could be inserted.

The street cards are filed vertically in alphabetical order under the names of roads and streets, and bear reference numbers to the detail points on the Ordnance Sheets and to the cards of immediately contiguous positions; the front of these cards is printed to represent a portion of the footpaths and roadway with horizontal ruled spaces, in which are entered the street number and a letter describing every building or premises along the road, whether connected or not.

Vertical columns at the sides marked "Distributor" represent low-tension cables, and as consumers' connections are made the watts applied for are to be entered under the sign A.B. or +. −. as the case may be, giving in conjunction with the low-tension side of the local sub-station card the state of the balance on each cable and the necessary information for deciding the polarity of each new customer. In the central squared portion circles and squares are marked in to indicate cables, pipes, or draw-boxes, disconnecting pillars, &c. On the back of the card detailed information is found concerning each numbered duct, cable, or other item: (*a*) Its position and depth; (*b*) size of pipe or box; (*c*) size of cable, type, maker's name, date of laying, and names of men responsible for the work, references to tests made and to the terminal points which it lies between.

Although the system outlined herein renders it easy to trace the details of any cable in the draw-boxes, it may be found convenient actually to label the cables with the leading particulars of their origin, supply, and size, at the time of jointing up. It will be obvious that in a simplified form particulars of the above-described system can be well adapted to recording the details of large private installations as found in factories, mines, and shipyards.

A Russian Electrolytic Copper Works.—It is announced that an electrolytic copper works will shortly be opened in the district of Kychtym. The works will have a capacity for turning out from 5,000 to 6,000 tons per annum, and arrangements have been entered into with the copper producers in the Urals for the supply of raw material.

Birmingham and District Electric Club.—At the annual meeting on Saturday, the following officers were elected as Council for the ensuing session:—President, Mr. George T. Wood; vice-presidents, Mr. Vincent E. Walters and Mr. G. A. Pope; treasurer, Mr. E. A. Morgan; secretary, W. G. L. Riddle, 82 New Street; committee, Messrs. John J. Inniss, Joseph A. Jeckell, E. R. Phillips, W. H. Whitehouse, G. O. Donovan, H. W. Brady, and J. Hill. Mr. Wood will deliver his presidential address early in January.

Non-magnetic Ship for Magnetic Investigations.—We understand that the Carnegie Institution of New York is building a vessel, every portion of which is entirely non-magnetic. The vessel is to be used for conducting experiments in the study of terrestrial magnetic conditions in all parts of the world.

SOME GENERALISATIONS IN THE DESIGN OF ELECTRICAL MACHINERY

THE Paper read before the Institution of Electrical Engineers on Thursday last by Messrs. J. C. Macfarlane and H. Burge, both of Messrs. Crompton & Co., Ltd., was an attempt to indicate the factors which limit the output which can be obtained from a given core size of a medium-speed dynamo or motor, and to show, by means of diagrams, the relations which exist between output and dimensions for machines designed according to average modern practice. The Paper was divided into three parts: namely, direct-current machines, three-phase induction motors, and three-phase alternators.

Direct-current Machinery.

Since the introduction of the interpole, the output that can be obtained from a given core size is no longer governed by the sparking limit, but depends on the permissible temperature rise. The well-known relation between the dimensions, the output factor, and the output per revolution of a dynamo-electric machine, given by Prof. S. P. Thompson, is as follows:—

$$d^2l = \left(\frac{60{\cdot}8 \times 10^7}{B \times q \times \psi}\right) \times \frac{\text{watts}}{\text{R.P.M.}}$$

where d = diameter of armature at face in inches, l = net length of armature core without ventilating ducts in inches, B = flux density in air-gap in C.G.S. lines per square inch (magnetic loading intensity), q = electric loading intensity (ampere conductors per inch of periphery of armature), ψ = ratio of pole arc ÷ pole pitch, and R.P.M. = revolutions per minute.

This relation can be expressed in a different manner, as shown by the equation below, in which the ratio ψ has been taken as 0·7.

$$B \times q = 870 \times 10^6 \times \frac{\text{watts}}{\text{R.P.M.}} \div d^2l.$$

This equation shows that, for a given ratio of pole arc to pole pitch, the product of the electric and magnetic loading intensities is proportional to the watts per revolution per d^2l. The relations between the quantity d^2l and the other quantities for large direct-current machines are shown plotted in the diagram of Fig. 1. In this diagram, quadrant 1 gives the relation between the output per revolution and the product of the magnetic and electric loading intensities ($B \times q$); quadrant 2

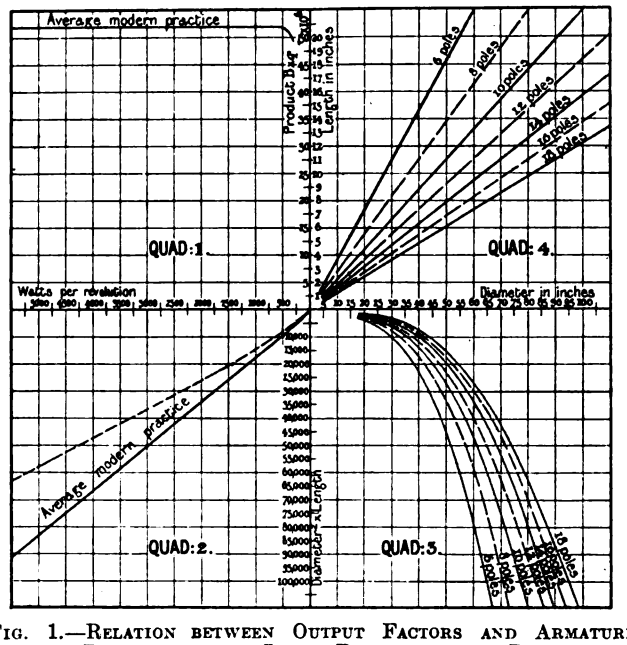

Fig. 1.—Relation between Output Factors and Armature Core Dimensions for Large Direct-current Dynamos.

gives the relation between the output per revolution and the size of the armature core (the d^2l); quadrant 3 gives the relation between the diameter of the armature and the d^2l value of the armature for various numbers of poles, on the assumption that the poles have square faces; and quadrant 4 gives the relation between the diameter and length of the machine for any number of poles. In making up these diagrams, a large number of interpole machines of modern design were considered, and the outputs were reduced to watts per revolution, and altered so as to correspond with machines with a 70 per cent. ratio of pole arc to pole pitch, and with square pole faces.

These diagrams enable the values of the product of the electric and magnetic loading intensities, the d^2l value, and the diameter and length of the armature core of a machine having

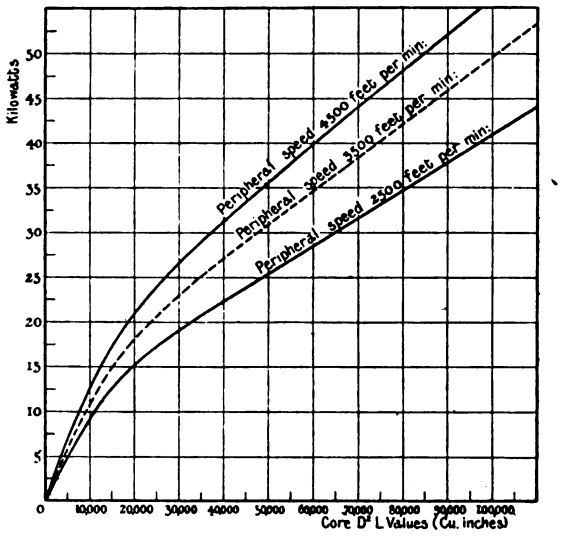

Fig. 2.—Permissible Kilowatts Loss in Armatures of Direct-current Dynamos.

square pole faces, to be obtained at a glance for any selected value of the output, and for any number of poles; but it is to be noted that this core size will only be large enough to give the selected output with a temperature rise not exceeding 75° F., provided the sum of the losses in the armature does not exceed the value obtained from the curve, in Fig. 2, corresponding to the d^2l value found. The values of the armature losses plotted in Fig. 2 were obtained from the average test results of a large number of machines, and represent the permissible armature losses for open-type machines at certain peripheral speeds, for a given temperature rise of 75° Fahr.

There are three directions in which to look for extension in the output limit of direct-current machines, namely, (1) improvements in the active materials used in the construction of the armature; (2) improvements in the ventilation; and (3) improvements in disposing and proportioning the active materials on the machine. Points 1 and 2 will not be considered in the following discussion, as they do not lie entirely in the domain of the electrical designer. In considering point 3, it has already been seen from the second equation that the output per revolution per d^2l is directly proportional to the product $B \times q$. It is obvious, therefore, that in order to increase the output per d^2l it will be necessary to increase the product $B \times q$, the value of which is influenced by the slot space-factor, the depth of the slot, the flux density in the teeth, and the relative cost of the active materials. The slot space-factor is increased generally by increasing the size of the slot, and this means that for a good slot factor the number of slots per pole should be small, and the depth of the slot great. The limit of width is settled by questions of humming, eddy currents in the pole faces, and the width of the interpole face. An increase in the depth of slot increases the slot space-factor, and allows more copper to be stored round the armature periphery, but the section at the root of the tooth and consequently the factor B are reduced. The maximum value of the product $B \times q$ occurs when the net width of copper in the slot is equal to the width of iron at the root of the tooth, and when the depth of slot is approximately equal to one-sixth of the armature diameter.

An expression can easily be obtained from the output equation given at the beginning of the Paper, which shows that the total magnetic loading of a machine (the total flux of all the poles) varies in inverse proportion to the total electric loading (the total ampere-wires on the armature periphery) for a constant output, and it may be observed that the amount of material in the magnetic circuit, *i.e.*, the iron and shunt copper, varies almost directly with this loading. Also the amount of

Digitized by Google

material in the electric circuit, that is, on the armature and interpole windings, varies approximately in direct proportion with the electric loading. From the above it is obvious that there is some value for the ratio of the total magnetic to the total electric loading, which makes the cost of the active material for any machine a minimum. This minimum value occurs when the cost of the material in the magnetic circuit is equal to the cost of the material in the electric circuit; that is, when the cost of the material in the armature winding, plus the cost of the material in the interpole winding, is equal to the cost of material in the shunt winding, plus the cost of the effective iron and steel in the magnetic circuit. In general, this occurs when the ratio of the total magnetic to the total electric loading lies between 250 : 1 and 350 : 1, approaching the lower limit when the machine is small and has an armature diameter great as compared with its length, and the higher limit when the machine is large and has an armature diameter small as compared with its length. The efficiency is a maximum when the loss in the magnetic circuit is approximately equal to the loss in the electric circuit, and this occurs when the ratio of the total magnetic to total electric loading is approximately the same as for the cost minimum. Obviously the total cost of active material will depend on the number of poles; but it is very difficult to set down any hard and fast rules as to the best value for the frequency. In the authors' opinion, 33 cycles should not be exceeded for medium-speed direct-current machines, and it is a waste of material to go below 20 cycles, where the number of poles is not limited by mechanical considerations.

In order to obtain an equation by which the iron losses could be readily estimated, some tests were made, and from the results obtained it appears that the core loss varies approximately as the 1·3 power of the frequency, and approximately as the second power of the density; therefore, if V_t = volume of the iron in the teeth in cubic inches, V_i = volume of the iron in the core in cubic inches, and W = total watts loss on the armature; then—

$$W = \frac{3}{10^{12}} f^{1\cdot3}(V_t B_t^2 + V_c B_c^2)$$

From the above considerations it is clear that the maximum output is obtained from a given d^2l value when the width of the copper in the slot is equal to the width of the root of the tooth, and when the depth of slot is approximately one-sixth of the armature diameter, the losses being kept within the permissible value by increasing the radial depth of the armature core. In quadrant 2 of Fig. 1 is given a dotted line curve which shows the increased outputs which may be expected from machines designed on these lines, the permissible losses being taken from the curve of Fig. 2, and the densities of the roots of the teeth being fixed at 135,000 C.G.S. lines per square inch. The actual iron losses were checked by the above equation. It is also seen that for the present prices of copper and iron, the cost of active material is a minimum when the ratio of the total magnetic to electric loading lies between 250 : 1 and 350 : 1. With regard to the commutator, this, with interpole machines, can be made much smaller than with non-interpolars, because of the diminished brush contact loss, but for ordinary direct-current interpole dynamos the average E.M.F. between the bars should not exceed 25 volts. As to the field system, good proportions for the interpole section are 50 per cent. of the core lengths, and 15 per cent. ratio of pole arc to pole pitch. With these dimensions the M.M.F. provided on each interpole should exceed the armature M.M.F. per pole by about 30 per cent. In concluding this part of the Paper, it may be observed that by using the proper multiplying factors, the diagram of Fig. 1 applies equally to direct-current motors and rotary converters.

THREE-PHASE MOTORS.

Unlike the direct-current machine, the core size of the asynchronous motor is not usually limited by heating considerations, but by the value of the leakage factor, on which the value of the maximum power factor depends. The leakage factor will be defined for this purpose as the ratio of the ideal light-load current to the ideal short-circuit current. The light-load current for three-phase motors (when wound with half as many coils per phase as poles) is obtained from the fact that the maximum value of the M.M.F. per pole is equal to the number of turns in one coil × the maximum value of the magnetising current flowing in that coil, this product being equal to a constant × the length of the air-gap × value of the maximum flux density in the air-gap. Values obtained in this way, however, will require to be increased from 40 per cent. to 80 per cent. in commercial motors, to allow for the magnetic resistance of the iron path of the motor and the increase in the air-gap density caused by slot openings. These are best allowed for by adding equivalent air-gaps to the actual air-gap; and for this purpose the authors gave a curve showing that the extra air-gap equivalent to the magnetic resistance of the iron circuit could amount to as much as 0·035 inch for a machine with a pole pitch of 20 inches. For a pole pitch of 10 inches, the equivalent air-gap amounts to about 0·018 inch. If it is assumed that the number of slots per pole per phase is proportional to the pole pitch, the air-gap equivalent to the extra resistance caused by slot openings amounts to about 10 per cent. of the actual air-gap. In order that the magnetising currents may be estimated for a whole series of machines, it now remains to suggest values for the actual air-gap δ_1 for any size of machine. The only consideration which influences the size of the air-gap in most cases is a mechanical one, and the curves, Fig. 3, give suggested air-gap values for machines as a function

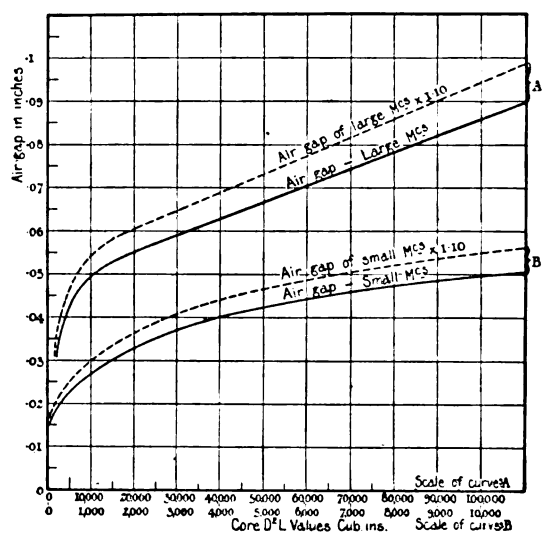

FIG. 3.—PROPOSED VALUES FOR AIR-GAP OF INDUCTION MOTORS.

of their d^2l values. After having found the values of the two equivalent air-gaps, these and the actual air-gap are added together, and if the sum is expressed by the symbol Δ, the value of the light-load current can be estimated from the following equation :—

$$C_o = \frac{0\cdot23\Delta B_{max.}}{S},$$

where $B_{max.}$ = maximum flux density in the gap (C.G.S. per square inch); S = the number of turns in one coil of each phase of the winding; C_o = ideal light load, or magnetising current in virtual amperes in each phase of the winding.

The value of the ideal short-circuit current per phase of a polyphase motor can be estimated by assuming certain values per ampere-turn per inch for the embedded and free lengths of the stator conductor. It has been pointed out by Hobart that the leakage per ampere-turn per inch of embedded length varies inversely as the pole pitch, and the authors of this Paper have found this to be true, provided the number of slots per pole per phase varies in direct proportion to the pole pitch. For motors with wound rotors and nearly closed slots the average value of the stator and rotor leakage per ampere-turn per inch of embedded length is about 2·3 C.G.S. lines for 18 slots per pole, and a 10-in. pitch, and the free length leakage is about 1 C.G.S. line per ampere-turn per inch. From these considerations the total leakage for any motor may be estimated, and from this, an equation for the short-circuit current can be derived; thus,

$$C_{SH} = \frac{0\cdot353N}{SN_2},$$

where C_{SH} = ideal short-circuit current in amperes per phase (effective value); N = total flux per pole crossing the air-gap (C.G.S. lines); and N_2 = leakage flux per ampere turn (C.G.S. lines). The value of the leakage factor σ will therefore be expressed by—

$$\sigma = \frac{C_o}{C_{SH}} = \frac{1\cdot05\Delta(46l + 2\cdot8T^2)}{T^2l}$$

where T = pole pitch in inches, and l = net length of stator core in inches.

From this equation it can be proved that for any size of machine with a constant number of poles (that is, for T^2l a constant) the leakage factor σ is a minimum when the ratio $\frac{l}{T}$ is equal to the quotient of T divided by a constant 16·4, provided Δ is also constant. The authors gave some curves, showing the values of

Digitized by Google

$\frac{l}{T}$ plotted as a function of T. One of these curves is represented by the above relation, and is meant to show the values of $\frac{l}{T}$, which will give the maximum power factor for a given d^2l and a large air-gap. This shows that for large values of the pole pitch, the ratio core length ÷ pole pitch should be large, and for small values of the pole pitch this ratio should be small. As the value of the total equivalent air-gap Δ is not constant, however, for a given T^2l value, other curves were given for medium and the smallest possible air-gap respectively; these curves give somewhat higher values for the ratio. The medium curve gives $\frac{l}{T} = 0{\cdot}6$ for T = 8; and for T = 19, the value of $\frac{l}{T}$ is 1·6. On this latter curve as a basis, the authors have constructed a set of diagrams to show the relation between maximum power and leakage factors, and the principal core dimensions for large induction motors. These are given in Fig. 4, and show at a glance the maximum power factor that can be commercially obtained from any core volumes, provided the motor has a wound rotor and is designed in accordance with the foregoing considerations. The output of induction motors for a given d^2l has not been so large

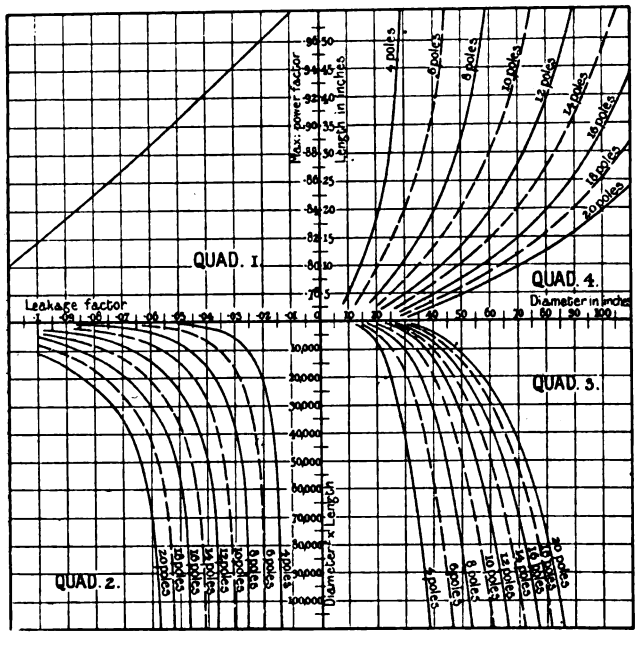

Fig. 4.—Relations between Maximum Power and Leakage Factors and Principal Core Dimensions for Induction Motors.

as that for direct-current machines. But in the author's opinion the advantages of high tooth density and uniform gap density in the latter machines are compensated for by the better distribution of the windings in an induction motor, so that it will be sufficiently near to take the curves in quadrant 2, Fig. 1, of d^2l values for direct-current machines as the limit to the size of induction motors for any output, provided the size is not already limited by power-factor considerations. When the number of poles is small, it is possible to reduce the core size until the limit of output is that of temperature rise only, although this tends to slightly reduce the maximum value of the power factor that can be obtained. In some cases it is convenient to use fractional pitch windings for induction motors, because in the case of high-speed motors, which usually have large pole pitches, the free ends of the winding become inconveniently long. With two-pole motors the authors consider that a fractional pitch of 50 per cent. should be used in almost every case, as this is easily obtained by winding the motor for four poles and reversing one of the coils in each phase. But this is almost the only case in which the use of the fractional pitch winding is advantageous.

Alternators.

The output to be obtained from the armature of a synchronous alternating-current dynamo is not in any way limited by questions of temperature rise, but is entirely limited by the permissible value of the potential rise from full load to no load when working on the maximum inductive load. In a similar manner to that adopted when dealing with direct-current machines, a formula connecting the product of the magnetic and electric loading intensities can be obtained. This is as follows:—

$$B \times q = 784 \times 10^6 \frac{\text{volt-amps.}}{\text{RPM}} \div d^2l$$

and it will be noticed that the only difference between the formulæ for alternating and direct-current machines is in the constant, which is smaller than for the direct-current machines.

In the diagram of Fig. 5, quadrant 1 gives the relation between the output per revolution and the product of the magnetic and electric loading intensities ($B \times q$); quadrant 2 gives the relation between the output per revolution and the size of the armature core (the d^2l); quadrant 3 gives the relation between the diameter of the armature and the d^2l value of the armature for various numbers of poles; and quadrant 4 gives the relation

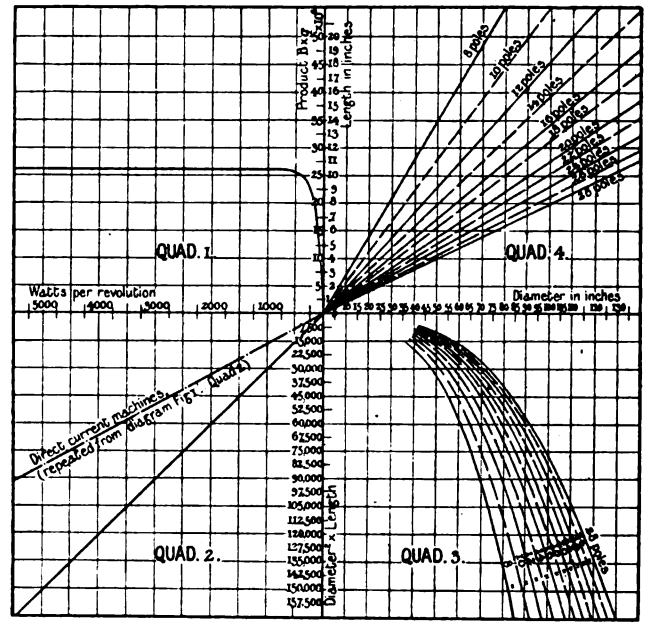

Fig. 5.—Relation between Output Factors and Armature Core Dimensions for Alternators.

between the diameter and length of the machine for any number of poles. By comparing the diagrams of Figs. 1 and 5, it will be seen that for the same output alternators are approximately twice as large as direct-current machines. The outputs of alternators are limited by the permissible potential rise from full load to no load, and this rise depends chiefly on the ratio of the field ampere-turns per pole to the effective armature ampere-turns per pole, which is usually about 4 to 1 in modern machines. The chief difficulty does not therefore lie with the armature, but it is a question of storing sufficient field copper on the alternator poles. This is due to the fact that the ratio of field ampere-turns to armature ampere-turns has to be very great.

The authors gave a method for calculating the potential rise, which took into account the resistance and reactance of both internal and external circuits, and then considered the possible means of increasing the output of alternators for a given core dimension. In the authors' opinion the old method of saturating a part of the iron section of the magnetic circuit might be made to give good results by careful design, and to produce this saturation, they suggest the use of a screw hole in the body of each field pole, extending almost to the pole face. The iron part of the pole above the tip of the screw becomes highly saturated, and this has the effect of flattening out the no-load characteristic. In order to obtain the best results the ratio of the reluctance of the iron part of the magnetic circuit to that of the air-gap should be made very high. This can only be done by reducing the air-gap density to the lowest possible value, by increasing the pole-face area, using semi-enclosed slots, and by reducing the length of the air-gap to a minimum. If the pole is over-saturated, so that the requisite E.M.F. cannot be obtained on full load, the length of the saturated part of the pole can be reduced by screwing the holding-on bolts further into the pole.

DISCUSSION.

Col. R. E. Crompton, who opened the discussion, after expressing his pride in the work of the authors, who are connected with Messrs. Crompton & Co., referred to the early days of dynamo design, when the core of the machine was considered a sort of adjunct of little or no importance. There were those present that evening who remembered the Gramme machine, with a few turns of iron wire for the core and a sort of pudding or winding surrounding it. It was this latter which was considered

Digitized by Google

the matter of real importance, the core itself being considered more as a sort of support for the winding, and the fact that it was made of magnetic material was of secondary importance. He was delighted to see the quadrant diagrams in the Paper; since they had been put into their hands, eight or ten years ago, an enormous amount of time had been saved by their use. The Paper, he thought, prevented it being urged against British engineers as a reproach that they were rule-of-thumb engineers. The results given in the Paper were not based upon the experience in the one works only, and he knew, although he was not so competent to criticise the Paper theoretically as many others, that the practical results obtained by the authors were second to none.

MR. C. C. HAWKINS put in a plea for a more definite terminology on this subject. As was very well known, revolutions per minute being an angular velocity, the quotient of watts or output divided by the angular velocity gave torque, and this might be regarded as the specific torque of the machine. It was this which the purchaser bought, and the machine had to give. The speed was, so to speak, a somewhat secondary matter, as the cost depended on this particular torque. The quotient of the specific torque divided by the d^2l, he would then suggest should be called the dimensional torque—*i.e.*, the torque which could be obtained for every cubic inch of d^2l. This dimensional torque appeared in the equation—

$$B \times q = 870 \times 10^6 \times \frac{\text{Watts}}{\text{R.p.m.}} \div d^2l.$$

The reciprocal he suggested should have the name of "size constant." This was the quantity which appeared in the first equation, and was then called the "output factor." Fig. 1 showed a flat curve for the product $B \times q$, and he agreed with the authors that for large machines it did practically become flat. When it was expressed in terms of lines in the air-gap per square *centimetre*, and ampere wires per *inch* of armature periphery, this quantity gave about 8·1 millions, and it might be definitely divided into $B = 9{,}000$ C.G.S. lines per square centimetre, and $q = 900$ ampere wires per inch of armature periphery. This was the value for average modern practice, but the authors' figure was 10 millions. He would suggest that this was obtained by $B = 10{,}000$ and $q = 1{,}000$, but he would like to know what quantities the authors had in their minds. He did not think the authors had quite sufficiently emphasised the influence of voltage. It had not so much effect on large machines, but it had a very great effect on small machines at high voltage. There was no real reason why a small machine should not give as large an output per cubic inch as the large one, except for indirect reasons, but there was a very great difference between a small machine at 500 volts and one which had to give 100 volts. This, of course, depended upon the space factor, which was mentioned by the authors, but rather in connection with the number of slots than the number of wires inside them and their insulation. He did not quite follow why the authors laid considerable emphasis on square pole faces. He took it that the desire was to have a square pole core as the most economical to secure a circular magnetising coil. Turning to alternators, he did not think that at the present time curves could be got out with nearly the same validity as they could for continuous-current machines. Probably in course of time such curves would come to be well established, but there were so many secondary conditions coming in to affect the values, apart from the power factor, which was to some extent taken in by using k.v.a. instead of kw. There came in, in addition, the question of frequency and also fly-wheel effect, both of which quite upset many calculations as to the best size of machine, or even the smallest size of machine. With regard to highly saturating the pole of an alternator, this was, of course, a recognised method of producing a small rise, but he took it that the authors considered that their special method would be a very useful means of getting over the difficulties of not being able to count securely on the quality of the steel, as the saturation could be varied. He would suggest, in order to get over the difficulty of making a machine having a small rise of potential, the employment of a Tirrill regulator. In conclusion, he criticised the authors' method of calculating the rise of potential with an alternator, in which the cross reaction of the armature was neglected. He thought that it was better to adhere to the long method which was first devised by Prof. Blondel. The great accuracy of this had been demonstrated before the Institution in the Paper read some years ago at the Glasgow Local Section by Messrs. Henderson and Nicholson.

DR. SILVANUS THOMPSON, F.R.S., added a reminiscence to those already mentioned by Col. Crompton. About the time Col. Crompton mentioned, a certain patent was taken out and a certain dynamo was constructed. The patent was taken out in two names, and both gentlemen afterwards became Presidents of the Institution. The main part of the patent was to substitute for the iron core of the Gramme machine a phosphor-bronze core. In his own lectures at the Society of Arts, he drew attention to the fact that the magnetic loading of a machine ran into millions, and that the electric loading was generally of the order of thousands. The ratio, therefore, of the whole magnetic loading to the electric loading was something of the order of 1,000 in any machine, small or large. Dr. Goldschmidt, in his recent Paper before the Institution, had assumed 800 as the ratio, and to-night they were invited to contemplate machines in which the ratio was something of the order of 250 to 350. This meant that armatures were now to be, relatively to the field magnets, three times as powerful as they used to be. They were getting more work from the copper relatively to the iron, and that clearly could not possibly have been obtained but for the general introduction of the auxiliary pole, so that it was clear that the immediate effect on practice of the introduction of auxiliary poles had been to enable them to make a smaller machine, and to make them more of copper, which was costly relatively to the iron, which was comparatively cheap. But it was not so in reality, because they used a much less weight of copper even now than they did of iron. The new rule that the total costs of the copper and iron of the active parts should be made equal, he thought, would have to be modified in some cases, as, for instance, when considering standard sizes and so forth, which would somewhat upset the calculations. He wished to know whether the authors were justified in the assumption that the cost of the material in each of the parts, electric and magnetic, was really proportional to the total electric and magnetic loadings, or whether this was only approximate. He also wished to ask whether the authors found, when they examined any standard line of modern machines, any difference in the ratio of the magnetic to the electric loading for machines of the same size that were intended to be used as generators and those intended to be used as motors. The authors, Dr. Thompson said, had found a new and, assuming it to be true, very valuable rule for the value of core losses, viz., that the core loss varies approximately as the 1·3 power of the frequency. Passing on to the portion of the Paper relating to induction motors, he expressed a doubt that the leakage per ampere turn per inch of embedded length always varies inversely as the pole pitch. Clearly it could not be true unless the number of slots per pole per phase was constant. If this varied, then all the values were different. With respect to the proposition for obtaining alternators with a flat curve by putting a big air space into the middle of the pole where a screw could be introduced, he confessed himself not convinced. It was not very many months ago that Mr. Miles Walker gave, he thought, conclusive reasons for preferring machines in which the flattening of the curve was got in another way, and in which the air-gap was made comparatively wide. Lastly, with regard to the rule for making the width of copper in the slot the same width as the root of the tooth, did not this cease to be true with very large sizes of machines where the tooth was nearly parallel, for it was only in the small sizes of machine that the root of the tooth was very much smaller than the crown? With respect to the predetermination of the leakage factor of induction motors, it was well known that there was a difference in the amount of self induction of end bends of stators and rotors according to whether they turned up near the iron or stood out straight. If they stood out straight, there was less self induction. Now if the end bends were made straight out instead of turning any of them up—as could be done by adopting a drum-winding—not only was there the advantage of the straight out bends having less self induction, but they began to get the advantage of mutual induction between the end bends of the rotor and those of the stator, and the mutual induction actually reduced the self induction.

MR. MILES WALKER (British Westinghouse Co.) first pointed out the difficult nature of the problem which the authors had attempted to solve in expressing graphically the relations between size and output for three-phase induction motors. He then drew attention to the curves given by the authors for the limiting values of the ratio l/T as by a function of the pole pitch. These values, he said, had been derived by means of several assumptions, and were given as representing the values which would give the lowest leakage factors. From these curves it was seen that with a pole pitch of 10 inches, the value of the ratio l/T should be about 0·6, which meant that for a T^2l value of 600, the length would have to be 6 inches. It might, however, for manufacturing or other considerations be more convenient to use the values 8·4 and 8·4 for the pole pitch and iron length respectively, in which case the ratio l/T would be 1. He had calculated the leakage factor which would be obtained with these last values, and found that it was different by only 4 per cent. from the value obtained with the authors' ratio of 0·6. Thus it was seen that the authors' minimum leakage factor for this particular case could be reached within 4 per cent. with a value of l/T, 50 per cent. greater than taken by them. From this it was evident that the curves for the best values of l/T given by the authors could only be considered as a means for obtaining the quadrant diagram of Fig. 4. It was also interesting to consider how far the figures of 2·3 and 1, as the number of leakage lines per inch, could be varied. Both were capable of very wide variations, and the former could certainly be varied 50 per cent. either way. This rather struck at the root of the ratio of l/T, and he was rather sorry it was so, because it would be of the utmost use to designers if they could generalise in this way, and if they could find some general formula by which they could prove that for a motor of a given output, a particular

Digitized by Google

length and diameter would be actually the best. The motors dealt with by the authors were said to be commercial motors. They might be commercial to manufacture, but were they commercial to sell? He rather thought a 500 h.p. motor at 50 cycles with a power factor of 0·87 (see Fig. 3) would be rather difficult to sell.

[Owing to shortness of time, Mr. Walker was asked by the President to send his further remarks for insertion in the *Journal*.]

Mr. G. G. Stoney (Messrs. C. A. Parsons & Co.) also related a reminiscence of the early days. He said there was a Siemens shuttle-wound dynamo in which the core was solid, and two Fellows of the Royal Society discussed why the core got hot. They finally decided that they could not give a reason, but determined to drill a hole down the middle and pass water through, and this was actually done. This was about 28 years ago. When Mr. Parsons started his high-speed dynamos running at 18,000 revs. per minute, nobody knew whether the magnetism would follow so fast. The late Prof. George Fitzgerald expressed the opinion that it would; as a result Mr. Parsons tried it, and we now knew it did. As Prof. Thompson had pointed out, the specific loading of armatures had been immensely increased by either compensated windings or interpoles, or combinations of both. In his own work he was getting over three times the specific loading with compensated windings than he had been able to get without them, and in addition, such a thing as shifting the brushes was now unknown. He was rather sorry that the authors had not discussed improvements in active material, as these were most important to electrical engineers. Within his recollection the hysteresis losses in ordinary armature iron had gone down one-quarter compared with the old days. They used to think that if they got iron which gave 1·2 watts per pound they had done very well; but now they could easily get iron to give 0·3 watts per pound, and with the special silicon steels—in which Mr. Mordey had done so much work—they could get down to 0·2 watts per pound, or one-sixth of what it was 20 years ago. At the same time, the specific resistance of the material was about six times higher, so that the eddy current loss was only about one-sixth. The authors had also purposely left out ventilation. Yet this was one of the most important things in a dynamo or alternator. One of the problems of the designer was to put the maximum of copper and iron and the maximum of ventilation into a given space. The authors stated that the output obtainable from the armature of a synchronous alternating-current dynamo was not in any way limited by temperature rise. This was also mixed up with ventilation, and he only wished it were true, because in his experience temperature rise was even more important than permissible rise of potential. Some alternators, he believed, had been rejected owing to excessive temperature rise. The Tirrill regulator had been mentioned, but his firm had been using the compensated alternator, which was described in the Paper by Mr. Laws and himself before the Institution last session, with very satisfactory results. From experience with this it was found that the lag due to the very small alteration of the magnetism was quite inappreciable, and he thought it would prove more satisfactory in connection with the compensating of alternators than the Tirrill regulator, as there were no moving parts whatsoever. The high saturation mentioned by the authors was, in actual commercial alternator design, a dangerous thing. If there was the smallest error in estimating the leakages, or if the material was not as good as might be expected, they failed completely to get the result desired, and especially so on an inductive load. For ability to run up the voltage a bit in case the drops in the mains were more than were expected, or that some portion of the system required higher voltage, it was most important that there should not be too much saturation. It also enabled them to deal with a lower power factor than was expected. He therefore cautioned all young designers of alternating-current machinery not to trust too much to saturation.

Mr. S. E. Glendenning (Messrs. Laurence, Scott & Co.) disagreed with the authors that deeper slots necessarily meant improved commutation. As a general rule, a machine with shallow slots, other things being equal, ran better than a machine with deep slots. More important was the design of the commutators; it was very easy to turn a good machine into a bad one by economising too much in the commutator. By making it too small, they could not keep the temperature low, on account of the C^2R losses, and if they made the current density too high the brushes were reduced to coke in the course of a few weeks. Again, if they put in too few sections, the limit of reactance voltage might be reached. He had not gone beyond 23 volts, and he thought that was quite high enough. He suggested that the method by which the output had been increased in recent years was by increasing the windage and cooling surface of the machine by somewhat increasing the diameter, and he had got results 35 per cent. higher than those given by the authors in Fig. 2, with a peripheral speed of 3,500, by boring a big hole in the core. As the authors had suggested that the radial depth of the iron should be great, it looked as if they had been working with rather small holes. With regard to materials, the new armature steels, when the price dropped, would be a considerable help, especially in high-speed machinery. At the present time, however, "stalloy," for instance, was about three times the cost of ordinary armature steel. It was possible with this material to reduce the core loss by 40 per cent. Again, there was the question of enamel-covered wire. This could now be got with a thickness of one mil, which would stand 1,000 volts, even with some bending. It would also stand solder heat for a considerable time. At present, for moderate gauges, enamel wire was about 30 per cent. dearer than cotton-covered wire. There was also another item which might help in reducing the cost of field windings, although hardly an increase in the output of the machine, viz., aluminium. Of course, for commutators it would never be used, as it was a bad friction metal. With regard to ventilation, some firms had experimented with fans on the armatures, and they had certainly succeeding in ventilating the engine room, if not in cooling the armature. The ventilation of the field coils had been improved by increasing the size of the ducts, and by keeping the coils well apart from each other.

The following written communications to the discussion have been received:—

Mr. T. Carter (Newcastle-on-Tyne) writes:—It is stated at the beginning of the Paper that neglecting armature copper loss, E.C. is the output in watts. The Paper includes dynamos and motors, and it is only in a dynamo that this statement is accurate, as in a motor some of the watts contained in E.C. are used up in overcoming windage, bearing friction, and core loss, and these may in small machines be a comparatively large percentage of E.C. With regard to the expression, "output per revolution" in the formulæ, this expression is correctly denoted as watts/r.p.m., but whenever it is given in words, it is expressed so as to have no physical meaning whatever. "Watts/r.p.m." expresses obviously a measure of the *work done per revolution* of the machine. It is therefore also closely connected with the tangential force existing round the armature circumference. From Quadrant 4 in Fig. 1, it is clear that the ratio of diameter to length for square pole faces is very nearly half the number of poles in the machine. This is a very easy rule to remember, and as in a line of machines there are usually two or more lengths for one diameter, it is usually accurate enough to take the mean value of the ratio for a given diameter as equal to half the number of poles. Finally the slot depth of one-sixth the diameter of armature seems so very far away from anything adopted in practice that the utility of the expression is quite doubtful. It is quite impossible to think of a slot, say, 10 inches deep in an armature of 60 inches diameter, and a slot of 2 inches deep in an armature 12 inches diameter seems also rather odd, unless the saturations are very different from what are now used. This may be possible with interpoles.

Mr. R. Livingstone (Messrs. Dick, Kerr & Co., Preston) writes:—In considering D.C. machines, the authors leave out of consideration machines without interpoles. At present commutating poles are used chiefly on high-speed or variable voltage generators and variable-speed motors, and ordinary generators and motors are still built without them. Economy is one of the first considerations of any manufacturing firm, so that it is evident that for ordinary machines commutating poles are not considered economical. The ordinary D.C. generator can be designed so that the full output, as limited by temperature rise, can be obtained with excellent commutation. The use of interpoles in such cases can hardly be economical. In the authors' Paper a density of 135,000 C.G.S. lines per sq. inch is given for the limit of tooth density. Many machines are running with an "uncorrected" tooth density 15 to 20 per cent. greater than this (at frequencies of 25 to 30 ~), and I should like to know the authors' reasons for keeping this density so low. The depth of slot will have an influence on the A.T. required on the commutating pole. A deep slot gives a high reactance voltage, and the high armature strength gives a large distortion of flux in the interpolar gap. These two factors influence the commutation adversely, so that more turns would be required on the commutating pole. Would not this affect the ratio of depth of slot to diameter of armature, and also the dotted line curve in Quadrant 2, Fig. 1? In variable-speed motors or generators the increase of volts between adjacent commutator bars due to field distortion becomes of some importance, and would put a limit to the depth of slot. The armature A.T. increase almost directly as the depth of slot, but the field A.T. would not increase, so that the ratio of armature A.T. to field A.T. would be increased.

Mr. P. R. Friedlaender called attention to the fact that some of the curves contained in the Paper were entirely dependent on the ventilation arrangements adopted, and although large improvements in this direction had taken place within the last few years, the possible limit had by no means been reached yet. He also remarked that the exact causes of the greater part of the iron loss in direct-current armatures were at present unexplained. It was well known that this loss was usually two or three times as great as that calculated from the hysteresis and eddy current constants of the iron, and this excess was probably due to additional eddy currents produced partly by the burring over of the discs during construction, and partly in the thick end discs used to support the armature and

Digitized by Google

in the magnet pole faces. In connection with their remarks on induction motors, the authors had not explained how they estimated the total flux per pole. Apparently they had assumed a sine wave space distribution of the flux, but this was not quite justified for normal motors.

DR. ALEXANDER RUSSELL also sent in a communication, in which he criticised some of the authors' formulæ. In the case of that for total iron loss, the effect of variations in the thickness and resistivity of the iron stampings had not been taken into account, and he found difficulty in accepting the empirical formula for leakage factor, as it did not consider the number of turns and the nature of the windings of the stator and rotor. In their deductions as to a "best ratio" for core length to core pitch, they had also apparently assumed that the equivalent air-gap did not vary with the diameter of the rotor. He then proceeded to indicate a method for arriving at a formula for demagnetising ampere-turns due to the current in the armature.

The authors will reply to the discussion in the "Journal."

ELECTRICITY SUPPLY AND DOMESTIC HEATING AND COOKING

Dublin Discussion

THE Paper on "Domestic Electric Supply (including heating and cooking) as affected by Tariffs," read by Mr. W. R. Cooper on November 26th, before the London meeting of the Institution of Electrical Engineers, was further discussed by the Dublin Local Section of the Institution last Thursday. In the paper itself, which was given at some length on page 725 of ELECTRICAL ENGINEERING of December 3rd, Mr. Cooper considered the various methods of charging which had been proposed from time to time in relation to a supply both for lighting and domestic heating and cooking. He condemned all existing systems, especially the maximum demand system, and proposed one involving the payment of a fixed sum per annum, based on the total wattage of the lamps installed, plus ¾d. per unit used. The latter portion of the paper dealt with electric cooking and domestic heating.

Mr. W. J. U. SOWTER (Chief Electrical Engineer, Bray) said that he agreed with the author's strictures regarding the maximum demand system, but he differed from the author in thinking that it had been educational to the consumer. On the contrary, Mr. Sowter was convinced that it had in some cases done actual harm to supply undertakings; consumers did not understand it, and no system of charging which the consumer cannot follow and be able to check his account can be regarded as satisfactory. In places where the maximum demand system existed it was a work of considerable difficulty to frame another scale to take its place. It was impossible to substitute a flat rate because such a rate would, in order to give satisfaction, have to be as low as the average charge per unit to the longest hour consumer. Mr. Sowter considered that the proposal of the author to base the charge upon the number of lamps fixed would be unworkable in practice. Consumers often changed their lamps or had additional ones installed without notifying the authority, and there would doubtless be endless disputes regarding this. Of course, the proper way to charge was by the number of lamps *used*, but this brought them back to the demand indicator. In the speaker's opinion, the most satisfactory way to use the demand indicator was that adopted by Mr. Leonard Andrews at Hastings, viz., the indicator was calibrated for 30 watt lamps, and a fixed charge per annum made for each 30-watt lamp indicated, plus a small charge per unit for energy consumed. Every consumer understood such a system. As the author pointed out, the chief objection to any method of using demand or rebate indicators was that no account was taken of the *time* the maximum demand occurred. It was there that the two-rate meter stepped in. In ordinary lighting stations, "peak loads" must exist, and all the engineer could do was to try to broaden the peak as much as possible, and charge a remunerative price for energy used at such times. That was exactly what the two-rate system did, and in the speaker's opinion it was, in spite of the increased cost of meters and extra complication involved, the most equitable system yet introduced. There was no reason why *per se* a heating device—say, an electric kettle—should be charged at a cheaper rate when used at "peak time" because it *was* a kettle and not a lamp. Regarding cooking by electricity, there was no doubt that there is a field for extensive operations in that direction, particularly in view of the high price of gas in the Dublin district. In order to emulate the energy of the gas company in that direction, it was necessary to adopt their methods by hiring out apparatus to consumers. Unfortunately, however, the very high cost of such apparatus militated against success. A complete set of electrical cooking apparatus cost at least £12, as against about £3 for the corresponding gas apparatus; further, the maintenance of such electrical apparatus was a costly item, so that altogether he was afraid that, although granted that the cost of energy in each case would be about the same, it would be necessary, in order to carry out the project commercially, to charge a rental many times greater than the gas company did, with the result that the public would not entertain the suggestions even of the most pursuasive and eloquent canvasser. Therefore, one could only hope that the manufacturers would be able in the near future to place upon the market cheap and simple apparatus to compete with gas cooking and heating stoves.

Mr. A. E. PORTE remarked that Richmond was a typical residential district, and that the bulk of the demand was for private house lighting. The load curves given in the Paper showed clearly the necessity of pushing the sale of energy for cooking and heating. He did not think that the cooking and lighting loads would overlap to any great extent, but if they did, then a meter which differentiated between the hours of supply, viz., a two-rate meter, would render it easy to frame an equitable scale of charges. For instance, in the Richmond case, during the winter months, the higher rate of charge might endure between the hours of 4 and 10 p.m., and in the summer from 8 to 10.30 or 11 p.m. Two-rate meters were expensive at present, but he thought that they might be made much cheaper. Mr. Porte thought that there should be a considerable field for the use of radiators in offices in large cities, which during the winter months would form a substantial day load. Regarding the proposed domiciliary visit necessary in connection with the scheme of charging based on the lamps connected, he (Mr. Porte) thought that such a necessity would render the system very unpopular, and he doubted very much whether corporate bodies could spend the ratepayers' money for the purpose of employing the necessary officials for the work. Of course, a private company had far more latitude in this respect. Turning to the subject of cooking by electricity, Mr. Porte referred to an electric oven invented by a Dublin man who, curiously enough, had very little knowledge of electrical matters. The oven consisted of a cylinder with shelves arranged round, over which a well-shaped cover fitted. The chief feature of this apparatus was that it was very thoroughly lagged, and the number of heating elements could be varied at will. In ordinary electric ovens their inefficiency was largely due to the number of times it was necessary to open or shut the door, and the very poor method of lagging. The apparatus then referred to would cook a large ham with one unit of electricity, and he thought that a considerable advance. Mr. Porte had had some experience with electric flat-irons, and found that an 8 lb. iron consumed 0·5 unit per hour, while a 14 lb. iron required 1 unit per hour. This was slightly higher than the cost for gas irons.

Mr. L. J. KETTLE (Dublin Corporation) said it appeared that "Tariff Reform" was still in the air. The suggested method of charging, according to lamps fixed, was no novelty, as it had been tried on the Continent, and abandoned in favour of an ordinary flat-rate. If, however, such a system were adopted he thought undertakers should charge for the candle-power irrespective of efficiency. He noticed that Mr. Cooper, in making his calculations concerning the cost of producing extra energy for cooking and heating, assumed a load factor of 25 per cent., but it seemed to Mr. Kettle that it would not be anything like so high. That being so, the whole argument fell to the ground, and cooking and heating should be charged at a somewhat higher rate than those suggested. Of course, if some arrangement could be made whereby such apparatus could be kept off the mains at "peak time," then energy could be supplied cheaply for heating and cooking. He noticed that in the table of costs of different methods of cooking given in the Paper, that oil was apparently only half the cost of gas; why, then, was gas used at all? It was, of course, purely a matter of convenience. That being so, electrical cooking for just the same reason would probably supersede gas cooking. Referring to the question of tariffs, he thought that the maximum demand system had been useful in making charges equitable between consumers, but, on the whole, a flat rate was likely to prove the more satisfactory, although not so satisfactory to the station engineer.

Mr. W. TATLOW (Messrs. Egan & Tatlow) saw no reason for the introduction of another new tariff, and thought that a tariff based on the number of lamps installed would prove particularly objectionable. The public would not take kindly to the intrusion of officials for the purpose of inspective installations. Such schemes paved the way for the "bogus" inspector, whose "inspections" probably would not be limited to installation and lamps. The speaker did not consider that the cost of separate wiring for heating and cooking would be great. In any case, extra wiring was essential. Contractors were not usually so liberal in their estimates of copper necessary for the lighting circuits. A radiator absorbing one kilowatt could not be attached to an ordinary pendant fitting, and must be wired up separately; why not therefore put in a separate circuit? Similarly, the supply authorities would have to instal a larger meter.

Digitized by Google

The course adopted by the Dublin Corporation—and doubtless it was a correct one—was to put in separate meters for such purposes. Concerning cooking apparatus, Mr. Tatlow, judging from his own experience, thought that the cook often needed improving as well as the apparatus; otherwise it would soon be ruined. Flexible cords were an objectionable feature, and if an alternating current apparatus could be devised consisting of a large magnet energised by the circuit, and the kettle, hot-plate, or other apparatus containing short circuited conductors were placed on top, the eddy currents induced would furnish the necessary heat. Such an apparatus, if practical, would be a distinct advance. Touching upon the question of heating buildings, he referred to the fact that in America the central station authorities carried out a good deal of heating, but by steam exhaust, which was distributed. This, of course, involved the location of the generating station in a central position.

Mr. P. S. Sheardown (Dublin United Tramways Co.) thought that there were no very definite views expressed in the Paper; the author simply suggested another method of charging without giving any proof of its benefits. He agreed with Mr. Tatlow on the wiring question. If a house was properly wired there should be no room for cooking and heating apparatus. Wiring for such apparatus should be cheap, because a drop of potential on heating circuits was not as serious as on a lighting circuit; therefore the matter was not so serious as Mr. Cooper suggested. Mr. Sheardown expressed himself in favour of the two-rate method, which he thought would lead to cooking and so on being conducted at other than "peak" times.

Mr. G. F. Pilditch (Chairman), in closing the discussion, agreed that the proper system was to use separate circuits with independent flat rates for lighting and heating. Gas consumers had no restrictions placed upon them, and he was afraid that if electrical undertakers imposed all kinds of restrictions on consumers they would not take it up. The cost of wiring was not a serious matter, but local authorities should have powers to wire up and let out cooking apparatus in the same way that the gas companies did. Mr. Pilditch thought engineers worried too much over the peak; they should endeavour to push heating and cooking as much as possible in order to level up the curve. Two-rate meters were complicated and expensive to maintain, and consumers using them always thought when the quarterly account was presented that they had used no energy at the higher price, and consequently that the meter was wrong. Electrical flat-irons were usually well used, and should be encouraged.

LONDON ELECTRIC POWER BILLS

London Electric Supply Bill.

THIS Bill came up for third reading in the House of Commons on Monday, and was the subject of considerable debate.

Mr. A. C. Morton, on behalf of the City of London Corporation, moved the insertion of a new clause providing that the promoters should obtain the consent of the City Corporation before opening the streets for the purpose of laying mains. Although Mr. Churchill, on behalf of the Board of Trade, was willing to accept this, Sir Luke White, as Chairman of the Committee which considered the Bill, expressed the opinion that if these powers were granted to the City, they would have to be granted to every other local authority. There was considerable general opposition to the clause, and on a division it was rejected by 170 votes.

The following new clause on the motion of Mr. Churchill was then agreed to: "From and after the date when the Council gives notice to purchase the undertaking of a supply Company, it shall not be lawful for that Company, except with the consent of the Board of Trade, to increase its charges for a general supply, as defined in the Schedule to The Electric Lighting (Clauses) Act, 1899. If at any time after the aforesaid date the Company makes any higher charge for electricity supplied to any consumer under agreement than had been charged for a similar supply under similar conditions during the period of twelve months immediately preceding that date, the consumer affected may appeal to the Board of Trade, who, if they consider that the increase is unreasonable, may make an order requiring the Company to reduce the charge accordingly, and any such order shall be binding on the Company."

A further alteration was made in the Bill, permitting the Companies concerned in the London (Westminster and Kensington) Electric Supply Bill to link up their undertakings with the promoters of the present Bill, and in this connection Mr. Churchill gave an undertaking that the Government would at the earliest possible moment introduce a Bill constituting the London County Council the purchasing authority of the Companies concerned in the other Bill. The alteration to the Bill in question renders the other Companies liable to all the provisions of the present Act.

Mr. W. Guinness moved an amendment to Clause 4, which provides that the route of mains shall be agreed between the Companies and the local authorities. The amendment in question gives the London County Council the same rights as the local authorities in this respect. There was considerable opposition to this on behalf of the borough councils, but it was eventually agreed to.

Mr. B. S. Straus, referring to the new schedule of prices for power supply in the Bill—namely, £6 15s. per kilowatt of maximum demand per annum, and 0·5d. per unit, moved that the price per kilowatt be £4 10s., which was the price inserted in the Bill as it originally came before the House of Lords Committee in the form of a bulk supply scheme. It was pointed out, however, that the original scheme provided for a tenure of 42 years, whereas now the Companies only had 23 years, and after Sir Luke White had mentioned that the price now in the Bill had been agreed upon between all parties, this amendment was withdrawn.

The following amendment on the motion of Mr. W. Guinness was made to Clause 15, which is for the protection of the London County Council:—

"(7) The said Council shall, for the purpose of section fourteen of the Schedule to The Electric Lighting (Clauses) Act, 1899, have, in addition to any powers, rights, and privileges possessed by it under the said section, the same rights, powers, and privileges as if they were the local authority for the said county. Provided that nothing in this sub-section shall be deemed to require the works or plans of a local authority who may be an authorised undertaker to be approved by the said Council."

A further amendment at the instance of Mr. W. Guinness was made to Clause 22 (the Purchase Clause), as follows:—

"Provided that this sub-section shall not apply in respect of any part of the undertaking of the Metropolitan Electric Supply Co. which may not in pursuance of this section be purchasable by the Council upon the terms specified in section two of The Electric Lighting Act, 1888."

A further amendment by the same member to Clause 22 was accepted for the purpose of making it clear that any companies not operating under the Electric Lighting Acts of 1882 should be purchasable equally with those who are.

Mr. Churchill then proposed two new sub-sections in Clause 22 in substitution of those in the Bill. These read as follows:—

"(3) The undertakings of the several London Electric Supply Companies within the county, including any lands, buildings, works, materials, and plant provided or constructed under the powers of this Act shall, if purchased by the Council, be paid for upon the terms specified in section two of The Electric Lighting Act, 1888, provided that if the Council give notice for purchase at the twenty-sixth day of August, one thousand nine hundred and thirty-one—

"(*a*) that part of the undertaking of the Charing Cross, West End, and City Electricity Supply Company, Limited, which is authorised by The City of London Electric Lighting Order, 1899, shall be purchased only upon the terms set forth in the said Order; and

"(*b*) the City of London Electric Company, Limited, shall be entitled to such additional compensation as may be agreed upon, or as may in default of agreement be determined by arbitration, for loss of net profits which might have been made by that Company between the said twenty-sixth day of August, one thousand nine hundred and thirty-one, and the eighteenth day of August, one thousand nine hundred and thirty-two.

"(4) The Council shall not be under any obligation to purchase so much of the undertaking of the Metropolitan Electric Supply Company, Limited, in the said county as is not purchasable by a local authority except such lands, buildings, works, materials, and plant as shall have been provided or constructed by that Company under the powers of this Act, but the Council may, if they think fit, purchase so much of the undertaking as aforesaid on such terms, if not agreed upon, as an arbitrator may think reasonable."

In moving these amendments, which were eventually agreed to, Mr. Churchill explained that the presence of the words "on equitable terms" in the instruction to the Committee, which had had so much stress laid upon them by the promoters, had not been intended to open the question of the purchase terms, but only to provide for those cases in which certain companies had a longer term than 1931, so that the County Council could purchase them at that date by giving compensation for the unexpired period.

Mr. W. Guinness moved an amendment providing that the London County Council should have powers, after having purchased all the Companies to sell the distributing system to the local authorities, but the Board of Trade objected to this, and the amendment was withdrawn.

In the same manner a further amendment by Mr. Guinness providing for the purchase of a local authority's undertaking by the County Council, where this was in competition with the

Digitized by Google

Company, at the same time the Company's undertaking was purchased, was also withdrawn.

Mr. GUINNESS then moved that three-fourths of the purchase money instead of one half, as proposed in the Bill, should be payable in stock and the remainder in cash. The Companies having agreed to make this concession, the amendment was agreed to.

The following sub-section to Clause 24, "Advances to Companies by Council," was added on the motion of Mr. Churchill :—

"(*d*) The Council shall not be obliged to advance any sum to a Company under this section unless they are satisfied that there is adequate security for the repayment to them of the sum to be advanced and for the payment of the interest thereon."

In this same connection, the following addition was made on the motion of Mr. W. Guinness :—

"It shall be lawful for the Council and any of the London Electric Supply Companies to enter into and carry into effect any agreement or agreements with regard to matters dealt with in this section, and any such agreement may contain any provision for the repayment to the Council of any sum which they may advance to a supply Company in pursuance of this section, notwithstanding the provisions contained in this section."

The Bill was then read a third time.

London (Westminster & Kensington) Electricity Supply Bill

On the third reading consideration of this Bill, a clause was added on the motion of Mr. Lambert on behalf of the Admiralty in precisely the same terms as one which had been accepted by the promoters of the previous Bill, for the protection of the Admiralty. The clause read as follows :—

"If the Admiralty are of opinion that the generation or use of electrical energy under or for the purposes of this Act by the Companies injuriously affects, or is likely injuriously to affect, any instrument or apparatus in or adjacent to the Royal Observatory at Greenwich, including the Magnetic Pavilion, or the efficient working of such instrument or apparatus, the Admiralty may, after such inspection and inquiry as they think proper, require that the Companies shall use such precautions, including insulated returns, as the Admiralty may deem necessary for the prevention of such injurious affection, and the Companies shall forthwith comply with such requisition. For the purpose of this section any person authorised in writing by the Admiralty shall have access at all reasonable times to the works and apparatus of the Companies, who shall give all due facilities for the inspection. Provided always, that in the event of any instrument or apparatus hereafter used in the said Observatory which may be of a different character and of materially greater delicacy than those used therein at the passing of this Act, the Admiralty shall consider, and may in their discretion determine, to what extent the powers of this section should be exercised, regard being had to the interests of the public as well as to the purposes of the instruments or apparatus as the case may be. The Admiralty Suits Act, 1868, shall apply for the purposes of proceedings in regard to any breach of the provisions of this section or for injurious affection of the said Observatory or instruments or apparatus."

Some minor amendments having been made, this Bill was also read a third time.

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY

IN order to remove sulphur from the metal in iron smelting furnaces it is necessary to have the slag free from metallic oxides, in particular from oxide of iron. The sulphur must be combined with calcium, and not, as is the case in other metallurgical processes, with manganese. The conversion of the iron sulphide and of the manganese sulphide into calcium sulphide can only take place in presence of a powerful reducing agent. In the Héroult electric furnace, calcium carbide is employed to remove the sulphur, and in the induction furnaces ferro-silicon is used. The desulphurising power is practically the same in both cases, but the use of ferro-silicon is more expensive. In the Héroult process the calcium carbide is made *in situ* by the action of the carbon electrodes on the lime slag. It does not, therefore, require to be first made and then added to the furnace charge, consequently it is found to be about 5s. cheaper per ton of iron smelted than if ferro-silicon were employed. There is also a danger in the use of ferro-silicon that the finished steel may contain too large a quantity of silicon. The employment of calcium carbide to produce a slag poor in metal has been patented by the Elektrostahl-Gesellschaft, German Patent, 163519.

According to *Stahl und Eisen*, 1908, p. 1906, the electrometallurgy of iron and steel has now passed out of the experimental stage, and is a recognised manufacturing process. There are at present

	Induction furnaces.	Arc furnaces.

	35	43

P. Askenasy, W. Jarkowsky, and A. Waniczek contribute an interesting note on aluminium carbide in the *Zeitschrift für Elektrochemie* of December 11th. Instead of starting with metallic aluminium and carbon to prepare their carbide, they heat strongly in an electric furnace a mixture of aluminium oxide and carbon. The furnace made of carbon plates was the one electrode, and the other electrode was a rod of carbon. Experiments were made to ascertain the best conditions for the formation of the carbide. The most successful experiment was one in which at 30 volts they employed a current of 600 amperes for one hour. With 40 volts and 200 amperes for 1½ hours the results were not so good. The carbide has a fine yellow crystalline appearance. A peculiar property of the carbide is that if it is heated for some time aluminium is obtained from it, and the carbide becomes black from the deposition of carbon. In one case, on heating some of the carbide for 55 minutes, 52·66 per cent. of aluminium melted out from it. It would appear that the carbide is produced only at high temperatures, but that at moderate temperatures the aluminium and carbon lie side by side. The facts now discovered throw light upon the experiments of Pring, who found, under certain circumstances when aluminium carbide was heated with metallic oxides, that aluminium alloys were obtained, and also that when the carbide is decomposed with water or acids the methane given off was invariably mixed with hydrogen. This means that aluminium carbide always contains some free metallic aluminium.

At a meeting of the Faraday Society, held on the 15th, three Papers were read. The first was by Dr. F. J. Brislee upon "A Redetermination of the Electrolytic Potentials of Silver and Thallium." The potential difference between a metallic electrode and a solution containing ions of the same metal is given by the equation

$$E_{\text{electrode}} - E_{\text{electrolyte}} = E_0 P_1 + \frac{kT}{nF} \log C_0$$

Where C is the ionic concentration of the solution surrounding the electrode, R the gas constant, T the absolute temperature, F the charge per gramme equivalent, and n the valency. The electrolytic potential, *E.P.*, is defined as the potential of a metal against a normal ionic solution of the same metal. The *E.P.* was measured by employing the calomel or hydrogen normal electrode, and determining the E.M.F. between the electrodes of the combination metal. The results obtained for silver were in both acetate and nitrate solutions +1·0757 volt. The most probable value of thallium was found to be −0·0425. Mr. H. Russell Ellis read a Paper on "The Formation of Graphite by the Interaction of Magnesium Powder and Carbonate." The author found in all cases when magnesium powder was heated with carbonates considerable amounts of graphite were formed. The third Paper was by Dr. E. Feilmann, upon "Colloidal Barium Sulphate." The method of preparing this substance was described.

CATALOGUES AND PAMPHLETS RECEIVED

ELECTRIC HOOTERS, BELLS, &c.—Pamphlets from Messrs. Marples, Leach & Co. describe the "Adnil" electric hooter for various signalling purposes, motor cars, &c., and a large and powerful motor-driven electric bell for factories, &c.

THREE-PHASE MOTORS.—A further pamphlet of the series being issued by Mr. G. Wüthrich deals with three-phase variable Oerlikon speed motors for two or four speeds, from ½ to 20 h.p., for pressures up to 500 volts 50 cycles.

ARC LAMPS.—Messrs. Johnson & Phillips have continued the series of new lists they are bringing out by the issue of a catalogue of arc lamps and accessories. Two sizes are included of the firm's patent shuntless single enclosed arc lamps for continuous and alternating current. The "Magnet-Juno" flame lamp is also dealt with, together with a special pattern of vertical carbon flame lamp (see ELECTRICAL ENGINEERING, Vol. II., pages 723 and 776), and a new 60–80-hour magazine flame lamp. A very complete range of accessories is included.

STARTERS, CONTROLLERS, AND RESISTANCES.—A new list of Ward Leonard rheostats, issued by Messrs. W. Geipel & Co., deals with a number of varieties of these well-known field rheostats, ordinary and solenoid motor starters, controllers, theatre dimmers, and also lift controllers, both of a continuous current solenoid pattern and the alternating current form described on page 762 of our last issue. The prices of motor controllers and starters appear to have been considerably reduced, and a useful stock sheet, with special prices for some of those which are in stock for immediate delivery, accompanies the list.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Dec. 10th, 1908

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

1907 Patents

22,868, **Regenerative Braking with Series Motors.** British Thomson-Houston Co., Ltd. (*General Electric Co., U.S.A.*). This invention is for a method of obtaining regenerative braking with continuous-current series traction motors and consists in connecting the armature and field of each motor in series as is usual, and varying the voltage across the field by means of a separate source of supply. This has the effect of fixing a definite speed, below which the machine runs as a motor, and above which, as a generator; in each case the machine runs with a series speed-torque characteristic. To supply the extra field excitation a homopolar machine, with a set of collector rings for each motor, is provided. With this arrangement the motors can be connected in series or parallel in the usual manner. At starting, the homopolar machine is used to strengthen the motor fields. Four claims, eight figures.

25,624, **Prevention of "Over-Commutation."** M. Walker. An improved form of brush for commutators and rectifiers or permutators is described in this specification. To prevent sparking, the collecting brushes are moved into such a position relatively to the magnetic field, that the induced E.M.F. in the short-circuited coil is sufficient to entirely reverse the current. If the E.M.F. is too large, however, "over-commutation" will occur, as the reverse current will be larger than the armature current. To prevent this the present invention provides for a double brush, between the two halves of which an electric valve is placed. The valve thus prevents the current from reversing while the coil is short-circuited. Five claims, eight figures.

25,655, **Manufacture of Conducting Filaments from Natural Earths.** E. von Seemen. This specification describes a process for the manufacture of conducting bodies from such substances as alumina, silica, lime, magnesia, or compounds of these. The substance is fused with a small quantity of an oxide of the iron group in the presence of oxygen. A substance made in this way, and consisting, for example, of 85 to 90 per cent. of magnesia, alumina, or silicate of magnesia, with from 15 to 10 per cent. of iron or chromium oxide, is a good conductor of electricity when cold. Three claims.

25,716, **"Venner" Time Switch and Solenoid Main Switch.** R. F. Venner and R. C. Griesbach. The "Venner" time switch adapted for use on arc-lighting circuits, and the pattern of solenoid-controlled main switch, for use with the above, are described in this specification. An illustrated description of this main switch was given on pages 44 and 45 of the Manchester Exhibition Supplement to Electrical Engineering of October 29th, 1908. Seven claims, five figures.

1908 Patents

3,369, **Detector for Indicating the Existence of High Voltage.** W. M. Thornton, H. W. Clothier, and A. Reyrolle and Co., Ltd. This apparatus consists of one or more condensers in series, with a spark gap. If one side of a condenser is connected to the wire or body to be tested, and one terminal of the spark gap, or of another condenser in series is connected to earth, a spark will occur if the wire or body is at a high potential. The charge to which the spark is due is purely inductive, and this renders the apparatus quite safe to handle. Fuses are connected in circuit to protect the apparatus. Four claims, nine figures.

10,764, **Storage Battery Plates.** A. O. Tate. This and the two following patents, Nos. 10,764 and 10,768, relate to the construction of storage battery plates of the Faure type. The plates described consist of strips of a porous insulating material, such as kaolin, which are grooved on their opposite faces so as to constitute flanges. The active material is located in these grooves, and thin strips of lead are interleaved between the grooved sections. All the anode strips are connected to one supporting and connecting rod, and all the cathode strips to a second supporting rod. The active material in the grooves of the porous strips is entirely covered in on the two sides by the anode and cathode strips respectively, and, therefore, cannot become dislodged. Evolved gases escape through the pores of the insulating material, which also admit the electrolyte. A simpler form of construction in which the active material is sandwiched between thin strips of insulating material and lead alternately, with side plates of porous material, is described in the second specification, and the third specification describes yet another alternative in which each lead strip, whether anode or cathode, is fixed in an insulating frame with active material on either side of the strip, supported by flanges in the insulating frame. These frames are assembled together, alternately anode and cathode, with porous insulating strips between as before. Eleven claims, fourteen figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

1907 Patents

12,747, Cowper-Coles. Electrodeposition of iron.
20,774, British Thomson-Houston Co. & Wedmore. Switches.
21,928, Richardson. Globe for electric lights.
25,669, Hausmann. Electrodeposition.

28,487, British Thomson-Houston Co. (*General Electric Co., U.S.A.*) Machines for coating wires with insulating material.

1908 Patents

112, Van Raden. Magneto-electric machines.
412, Steynis & Chaumat. Production of ozone.
741, Electrolytic Alkali Co., Connor & Stubbs. Treatment of resins, wax, gums, &c., with chlorine.
892, Crompton & Co., Macfarlane & Burge. Alternating current induction.
1,304, Geissinger. Electrical temperature regulating apparatus.
1,950, Kingsbury (*Bell Telephone Manufacturing Co.*) Gravity switches for telephones.
1,956, Edwards. Joints of tramway rails.
2,222, Messier. Electric motor.
4,657, Ruzicka. Manufacture of resistances.
5,596, Kent, Lacell, & Silica Syndicate, Ltd. Mercury and other vapour lamps.
9,636, Siemens-Schuckertwerke Ges. Fittings for lamps.
9,762, Ruzicka. Manufacture of resistances.
9,763, Ruzicka. Manufacture of resistances.
9,832, Peters. Safety-fuses for switchboards.
9,876, De Sainte-Clare. Variable speed gear for electric automobiles.
10,104, Plumb. Signalling systems for mines
10,269, Ruzicka. Arc-lamp.
11,710, Siemens & Halske Akt.-Ges. Manufacture of a plastic mass from tungsten compounds.
12,420, Paulin & Fortune. Telemotor apparatus for ships' steering gear.
15,490, Haber & Koenig. Production of compounds of oxygen and nitrogen.
15,819, Aitken. Telephone cordless switchboards.
17,205, Bradburn. Telephone apparatus.
17,250, Hickie, Brentini, Manzetti & Brentini. Railway systems.
17,414, Siemens Bros. Dynamo Works & Kieffer. Ventilating the rotors of dynamo-electric machines.
17,509, Regina-Bogenlampenfabrik Ges & Hanisch. Arc lamp.
18,216, S. P. (Suchostawer Patents) Syndicate & Sayers. Surface-contact system of electric traction.
21,603, Allegemeine Elektricitäts Ges. Devices for protecting transformers, cables, &c.
22,516, Miess. Incandescent vapour lamps.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

1908 Patents

23,348, Gallagher. Statement delivery apparatus for meters.
24,581, Allmänna Svenska Elektriska Aktiebolaget. Means for regulating polyphase commutator machines.

Expiring Patents

The following patents expire during the current week after a life of fourteen years :—

24,876, of December 21st, 1894, **Electric Winding Mechanism for Meters and Clocks.** H. Aron. This device consists of an electromagnet and an armature pivoted between its poles. The armature carries a click which engages with a ratchet wheel geared to the main spring of the clock mechanism.

25,048, of December 24th, 1894, **Junction and Sealing Boxes for Cables.** G. H. Nisbett. This patent covers the provision of a separate water-tight chamber in the base of junction boxes, wall plugs, and other fittings into which a hydroscopic cable (such as a lead-covered paper cable) can be led and sealed.

CORRESPONDENCE

A COMPARISON OF THE BRITISH AND GERMAN ELECTRICAL INDUSTRIES.

The Editor of ELECTRICAL ENGINEERING.

Translation.

SIR,—Mr. Mordey's very interesting address, published in your issue of November 26th, expresses views which, in some respects, call for contradiction on the part of one conversant with both English and German conditions. First of all is the widespread belief in your country that the wages in Germany are lower than in England. For a number of years this assumption has no longer been correct in respect of most trades, particularly for skilled workmen. A comparison between the contracts of the Trade Unions and the wages lists for German workshops shows this clearly. This explains in a far simpler way than Mr. Mordey does why the cost of wages per unit is higher in Germany, the more so if the higher "social" allowances (sick and accident funds, and old age pensions) are added. Likewise the considerably lower costs per car mile in Germany must be attributed not to the cheaper wages, but partly to the fact that in Germany trailers are used very much, by which 25 per cent. of the staff expenses can be saved. The fact must further be taken into account that, owing to the German Sunday, with its more than double traffic, the staff, and consequently the necessary wages per car mile, are used more profitably.

Finally, Table II. in your abstract of the Paper obviously does not include the giant power stations of our mines, built in recent years, which feed the surrounding mines, ironworks, mechanical engineering works, &c., which are not included in the statistics used as they do not deliver current to everyone, but only to a few large consumers. In England, however, such mines and ironworks are very frequently supplied from public high-pressure power stations. A great mistake is made if the conclusion is drawn from Mr. Mordey's statistics that the *use* of electricity in Germany is less than in England. This only applies to lighting and public central stations, and not to power supply and collective generation of electricity.

The mistake is still greater if the smaller application of electricity in Germany, which is asserted, is assumed to imply that the electrotechnical *industry* in Germany—that is to say, the manufacture of electrical machines, cables, and apparatus—is behind that in England. The Briton who really knows the outputs of both industries will not be able to deny that the German one is superior.

It is, perhaps, not uninteresting to examine the reasons why the prices for electrical energy in Germany are, as Mr. Mordey very rightly states, considerably higher than in England.

(1) Coal is dearer and wages much higher, as are also the amounts to be paid to the towns for licences.

(2) Our electricity works pay on the average higher dividends, as a comparison of the share lists will show.

(3) The cost of putting up the works is higher. Here central stations are built more elegantly, the floor and walls are tiled, and windows are designed to give abundance of light and air. The buildings are built with technical architectural adornment, and the switchboards are decorated in a more ornate, but yet practical manner. Everything is bright and polished; there is no speck of dust, and no rust. No money is spared in this, for, apart from æsthetic considerations, such an arrangement is a good investment. Our experience shows that the men pay greater attention and care to their machines and the station if they are encouraged by the clean and attractive appearance of the rooms.

Then, again, our industry is in the position to dictate higher prices by tariffs and cartels. It is compelled to do so by the higher burdens of wages and the social conditions. This explains how, in the tenders for supplying the two 5,000-kw. turbo-generators for the London County Council, the only competing German firm made the highest offer—£20,350 dearer than the cheapest, and £6,463 dearer than the dearest English firm. Thus it comes about that the German firm for which I worked some time ago can never compete in price with English manufacturers, but obtained its numerous contracts only by reason of its superior manufactures.

Nevertheless, among English electrical men we still hear the cry that "the Germans cut the prices."

HUGO HERZFELD (*Dipl. Ing.*)

11 Lützowufer,
Berlin.
December 9th, 1908.

[To avoid confusion of names, we should explain that the writer of the above letter is not Dr. Rudolf Herzfeld, late of the Electrical Co., Ltd., and now with the General Electric Co., Ltd.—ED. E. E.]

THE CARDIFF TELEPHONE EXCHANGE.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—Referring to Mr. T. Devereux's article of December 3rd on the new C.B. Exchange at Cardiff, and dealing with the two-way junctions, I see he states that the calling relay of the incoming circuit is actuated by a loop through the distant operatives' telephone. I should like to ask Mr. Devereux what junctions these are "incoming from," as with all C.B. exchanges this is impossible, owing to the secondary condenser used in the operators' headset circuit chiefly to prevent this very state of things from occurring.

Yours faithfully,
A. J. PEARSON.

Glasgow,
Dec. 9th, 1908.

[We have submitted this letter to the author of the article, who writes us as follows:—In reply to the first point raised by your correspondent with reference to the calling relay on the "two-way" junctions, it should perhaps have been stated that these junctions are arranged for working to magneto-exchanges.]

LOCAL NOTES

BECKENHAM: *Charges for Electricity.*—The Council has decided that existing and new "free" wired consumers shall be allowed to have transformers installed and their premises fitted with high efficiency lamps on payment of a fixed charge of 2s. per lamp per annum to cover wiring rent and the cost of the transformer and fixing. The consumer to supply lamps and to pay the meter rent as heretofore. Existing consumers are to enter into new agreements embodying these terms. The present flat rate of 5d. per unit for electricity supply to be continued, but an intimation is to be given to consumers who elect to change over to high efficiency lamps that if in consequence of the introduction of these lamps the revenue is insufficient to enable the Council to carry on the undertaking without loss the price may be increased temporarily. A Sub-Committee have had before them the question of an entire alteration in the system of charging, but after consulting Mr. Manville and on his advice they recommend that the flat rate be continued.

"*Linking Up.*"—The South Metropolitan Electric Light & Power Co. have suggested to the Council that the engineers of the two undertakings should meet with a view to arranging linking up, and this has been agreed to.

Digitized by Google

BOURNEMOUTH: *Public Lighting.*—In October the Electric Lighting Committee was requested to consider what further steps could be taken to extend the hours during which the public lamps are kept lighted. The Committee has now presented a further report, in which it is stated that the total cost for one year of an extension of time for the whole of the borough for one extra hour's lighting every night, would be £550. The extra cost of all-night lighting would be £2,522. The Committee, however, report that the present arrangements are sufficient for the requirements of the public, and the Corporation have adopted the report.

BRADFORD: *Extension to the Electricity Plant.*—Extensions to the value of £50,000 for the electricity plant are contemplated. Mr. Thomas Roles, the City Electrical Engineer, has reported upon the matter, and points out that the present full-load capacity of the Valley road generating works is 7,880 kw., but, owing to the limitations of the condensing plant of one of the sets, the actual full-load capacity is 6,800 kw. Any further demands made upon the works, therefore, would have to be made up by overloading the slow-speed engines. There is also a 300-kw. high-speed generating set at the Sunbridge road sub-station. The maximum load during the present winter was reached on November 19th—namely, 6,597 kw.—and the margin is considered to be too small to meet deficiencies. Mr. Roles therefore recommends the installation of two extra high-tension alternating-current turbo-generators of 3,000 kw. capacity each, together with two cooling towers and two water-tube boilers each, with an evaporative capacity of 18,000 lb. per hour, with chain grate stokers, superheaters, &c. The total cost of the scheme, including extra high-tension switchgear, &c., is put at £50,300. We published an advertisement for this plant in our last issue.

BRADNINCH: *Electric Supply.*—The Bradninch & District Electric Supply Co. are now supplying electricity in the district, and street lighting was inaugurated last week.

BRIGHOUSE: *Bulk Supply.*—The Local Government Board has sanctioned a loan of £3,940, the cost of the sub-stations which the Council has erected in order to take a supply in bulk from the Yorkshire Electric Power Co.

CHELTENHAM: *Electricity Works Assessment.*—The Assessment Committee has reduced the rateable value of the electricity undertaking from £4,850 to £3,200. Hitherto the assessment has only been £1,800, and the new figure of £4,850 as proposed by the Assessment Committee was appealed against, with the above result.

CHIPPENHAM: *Electric Lighting.*—As the Council's electric lighting order can only be transferred to a company by means of a further provisional order, it is not thought advisable to incur the expenditure which would be involved owing to the small size of the undertaking which would be necessary. The Council, therefore, have agreed to a non-statutory company being started on the conditions that a member of the Council is appointed to the Board, and that the Council gives its consent to the opening up of roads, &c. It is further stipulated that no overhead wires are to be erected without the consent of the Council.

COLCHESTER: *Overhead Wires.*—An application is to be made to the Board of Trade for sanction to erect an overhead feeder from the power-station to Hythe Quay.

COOKSTOWN: *Electric Lighting.*—A proposal has been placed before the Council by a firm of electrical contractors for the installation of an electricity generating plant, but the Committee which was appointed to consider the matter has reported that they are of the opinion that there is not sufficient guarantee of an adequate consumption to justify the scheme being adopted. Further consideration of the matter has been adjourned until the next meeting.

DOUGLAS (I.O.M.): *Proposed Electric Tramway.*—A proposal by the Manx Electric Railway Co. for converting the horse tramway on the promenade to electric traction has been rejected, the reason given being that the Council think it inadvisable to lose control of this service.

DUBLIN: *The Electrical Undertaking.*—The Electric Lighting Committee have presented their report for the quarter to September 30th, in which they state that the number of consumers has increased during that period from 1721 to 1844. Although the applications for connections are increasing owing to the introduction of metal filament lamps, the demand shows a tendency to diminish for this same reason. The Committee, however, have every hope that this method of cheapening the use of electricity, will bear good fruit within the next 12 months in regard to the number of units sold. The Committee also report favourably with regard to the increasing use of electric motors for industrial purposes, and in this connection point out that the present varying rate for power is not working so satisfactorily as had been anticipated. Some prospective consumers had suggested that a special low rate for the summer months would be advisable, and accordingly the Committee fixed 1d. per unit for power purposes as the charge during six months of the year, with 1½d. per unit for the winter and autumn six months. This, they say, has not brought about any appreciable extra demand during the summer months, and the Committee have decided, subject to the approval of the Corporation, to adopt a uniform rate for power, heating, and similar purposes throughout the year from March 31st next, of 1¼d. per unit. This rate is a fraction under the present average for the year. The estimated expenditure for the year to March 31st, 1909, is £58,491, and the revenue £61,391. The actual income for the six months to September 30th was £24,785, and the expenditure £29,929.

DUDLEY: *Tramway Agreement.*—The agreement with the Tramway Company for the lease of the local tramways has now been completed, and awaits ratification in the Bill which has been deposited in Parliament. The tramway company will bear the taxed costs of the Bill.

DUNDEE: *Tramway Accounts.*—The accounts for the first half of the current year of the tramways undertaking show an income of £32,019, which is £148 below the estimate, and an expenditure of £19,978, which is £329 less than the estimate. The receipts show an increase of £1,454, compared with the corresponding period of last year.

GLASGOW: *Tramways and Street Widenings.*—A provisional order, which the Corporation propose to introduce into the next session of Parliament, deals with various matters, including new tramways. One of the clauses under this head has relation to the acquisition of portions only of properties required for the purpose of new tramways, and an effort was made by one of the Councillors to compel the Corporation to acquire the whole and not portions of such properties. Only two members, however, were in favour of this, and the model clause was inserted.

Proposed Tramway Abandoned.—In deference to the protest of the officials of the University, the Corporation has decided to abandon the proposed tramway running along the road skirting the University grounds. It had been pointed out to the Tramways Committee that the running of tramcars along this road would disturb the work and teaching of all departments where delicate instruments are in use.

HAMILTON (N.B.): *"Free" Wiring.*—A provisional order authorising the Council to spend money on "free" wiring is to be promoted.

HARROGATE: *Underground Telephone Wires.*—Permission has been given to the National Telephone Co. to lay underground telephone cables in certain part of the town.

KIRKINTILLOCH: *Opposition to Proposed Tramways.*—The Merchants' Association has unanimously decided to ask the Town Council to abandon the proposal recently put before the Glasgow Corporation for an extension of the tramways system of the latter to Kirkintilloch, on the ground that such an extension would be disastrous to the shop-keeping interests of the town.

LONDON: *London County Council.*—The Highways Committee report having had under consideration the question of rearranging the plant at present installed at the Elephant and Castle sub-station in order that sufficient power may be provided for working the Victoria Embankment tramways, and also the lines which are to be laid over Blackfriars Bridge when it is widened. Experience has shown that it is advisable that the Victoria Embankment lines should be worked from the Elephant and Castle sub-station as a part of the southern system, instead of, as at present, from the Holborn sub-station as a part of the northern system. At the present time, in the event of a fault occurring at the Holborn sub-station, the car services on the Victoria Embankment tramways are affected, with the result that the whole of the services on the southern routes, which run to the Victoria Embankment, are interfered with. The capacity of the existing plant at the Elephant and Castle sub-station is insufficient for the working of the additional lines, and it is proposed that two 1,500 kw. motor generators should be erected in place of the four 300 kw. motor generators at present at the station. The motor generators displaced will be transferred to certain of the outlying sub-stations. The total cost of the work is estimated at £19,000, of which about £3,000 will be chargeable to maintenance account and about £16,000 to capital account. None of the expenditure will come into charge during the current financial year, and provision for the expenditure on maintenance account will be made in the annual estimates for 1909-10. It is pointed out that by installing larger machines at the sub-station not only will the cost per kilowatt of capacity be less, but the traffic conditions will be considerably improved: further, if the lines on the Victoria Embankment were to continue to be worked from the Holborn sub-station when they are extended over Blackfriars Bridge, expenditure on capital account, amounting to about £25,000, would be required for new machines, switch-gear, and cables at that sub-station: so that the proposed rearrangement of the plant at the Elephant and Castle sub-station will represent a considerable ultimate saving.

London County Council: Tramways.—A deputation from the Lewisham Borough Council and the New Cross, Brockley, and Crofton and Sydenham and Forest Hill Tramways Committees have waited upon the Highways Committee of the London County Council urging the construction of the authorised tramways between Lewisham High Road and Forest Hill. No definite reply was given by the Highways Committee, although it was understood that the Council intend to construct the line as soon as convenient.

Digitized by Google

Bermondsey: New Tramways.—The Borough Council have formally consented to the electrification of the tramways from London Bridge to Deptford, subject to various street widenings being carried out at no expense to the Council. The estimated cost of the widenings in Bermondsey is £63,850, of which £40,250 represents the cost of acquiring property.

Stepney: Smoke Prevention.—In July last the Council allowed the British Fuel Economiser & Smoke Preventer Co. to fit up two sets of their apparatus for one month, to prevent any possible smoke nuisance at the Electricity Works, in each of two boilers, and agreed that if the apparatus fulfilled its guarantee, it was to be taken over by the Council on payment of £105. If the test proved unsuccessful, the Company were to remove the apparatus. The Electric Supply Committee have had submitted to them the report of the Electrical Engineer, with the result that the Committee say there is every reason to believe that the Company will not have fulfilled the guarantees within the period of trial, and they have decided that, should this be so, and should the Company be desirous of continuing their experiments for another month, they should be accorded an extension, on condition that it is granted without prejudice to the existing contract and guarantees, which are to remain in full force and effect, and on condition that the Company will not use more steam than the Engineer deems sufficient to obtain a successful issue.

LOUGHBOROUGH: *Expert Advice.*—Mr. J. F. C. Snell, Consulting Engineer, of London, has been retained at a fee of 60 guineas, plus first-class travelling and out-of-pocket expenses, to report upon the financial position and future management of the Council's electricity undertaking.

LOWESTOFT: *Electricity and Tramways Undertaking.*—At the last monthly meeting of the Council, it was reported that there had been a loss of £1,900 on the year's working of the tramways undertaking to September 30th, and £200 loss on the electricity undertaking. To meet the former deficiency, it has been decided to raise certain fares. The loss upon the electricity undertaking is solely due to the high price of coal, which has cost £872 more than in the previous year.

MALDEN & COOMBE: *Electric Lighting.*—The County of London Electric Supply Co., who hold a provisional order for this district, have informed the Council that they hope to commence works next spring. The Council are dissatisfied with this reply, as they state that the company has repeatedly shelved the matter, and the correspondence with the company is to be placed in the hands of the Board of Trade.

MEXBOROUGH: *Damage by Surface Contact Tramways.* In the Rotherham County Court on Friday, a cab proprietor was awarded £10 10s. damages owing to his horse having been injured in February last by treading on a stud which proved to be "alive." It will be remembered that the line has now been converted to the trolley system.

MIDDLESEX: *London United Tramways Co.*—The Councils of Ealing, Acton, Chiswick, and Hanwell are forming a deputation to wait upon the Board of Trade, together with the Members of Parliament for the districts, in respect of the alleged noise caused by the cars and track of the London United Tramways, Ltd. The Board will be asked to interfere, and take the necessary action against the company to prevent the continuance of the noise complained of.

MORECAMBE: *The Tramways Purchase.*—Arbitration proceedings have been taking place in London with regard to the purchase by the Corporation of the horse tramways in Morecambe. Major Cardew is acting as arbitrator, and the claim made by the company amounts to £16,000.

NEWCASTLE: *Noisy Tramcars.*—The General Manager of the Corporation tramways undertaking, Mr. E. Hatton, has reported to the Tramways Committee in reference to the noise made by the tramcars. Mr. Hatton points out that it is absolutely impossible to carry heavy weights on steel tyred wheels, or any form of metal, over metal rails without making any noise, although if the rails were laid in a more or less flexible manner, the vibration and noise would be partially deadened. The Newcastle track, however, he adds, is laid in a very rigid manner, and so far as the track is concerned, very little can be done to abate the present noise. With reference to the cars, most of the noise has arisen from the wearing of the pinion gearing, and the cars are being overhauled in this respect. Another source of noise is that the magnetic brakes are suspended from the cars by springs, and until some device has been introduced to operate the brakes in some other manner, Mr. Hatton has no recommendation to make which would not sacrifice efficiency. It is probable that a sub-committee will be appointed to deal with the matter.

NEWPORT: *Trackless Trolley System.*—Mr. H. Collings Bishop, General Manager of the tramways undertaking, has reported in favour of the adoption of the trackless trolley system for the outlying districts, to be worked in conjunction with the present tramway undertaking. In a report which Mr. Bishop has presented, he gives detailed figures of the estimated cost per mile of the system, including capital charges. He recommends the adoption of the trackless trolley system upon six routes inside the borough, and four routes outside the borough, making in all a total of some 12 miles, and his figure for the total cost of the equipment per mile, exclusive of cars, but including overhead work, cables, and contingencies, is £1,500. The cost of eight cars is put at £5,000.

NUNEATON: *Light Railway Scheme.*—Estimates have now been prepared of the cost of the proposed light railway between Nuneaton and Bedworth, a distance of three miles, the figure being put at about £50,000.

SOUTH SHIELDS: *Wayleaves to Power Company.*—It is stated that in consequence of the Corporation wishing to charge £250 wayleaves to the Durham Electric Power Co., for supplying the Hanton Coal Co., a clause will be proposed in the Bill deposited for next session, authorising the Company to take their mains through the Borough for this purpose, free of charge. We understand, however, that the Corporation have invited the parties to a round table conference in order to endeavour to arrive at an amicable arrangement. The Coal Company have offered £20 against the £250 asked by the Corporation.

SWATOW (CHINA): *Electric Supply.*—The *Hong Kong Daily Press* states that Swatow is in the peculiar position of having an electric installation, but no light. The undertaking, which started so well a year or two ago, is now closed down, and the plant is lying idle. The Chinese company which owns it is averse to foreign capital being invested in the enterprise, with the result that all attempts of Europeans to obtain control of the undertaking have proved unavailing. When the company commenced lighting, it had only contracts for 300 lights, but within three months that number had grown to 900. When the company ceased working on the first occasion it was supplying some 1,700 lights. It was re-started, but the works have since been closed down. The light was remarkably cheap, perhaps too cheap (says our contemporary), the charge being only a dollar per month per lamp, and it is declared with confidence by those who ought to know that at $1·50 per lamp the undertaking would have paid even on the existing basis. But lack of capital handicapped the work, and as shareholders who had already paid out $30,000 beyond the stated capital refused to contribute further, there was no other recourse but to shut down the works.

TAUNTON: *Condition of Tramway Track.*—A report has been prepared by Mr. J. S. D. Moffett, Manager of the Rochdale Corporation Tramways, upon the condition of the tramway track of the Taunton Electric Traction Co., Ltd., on behalf of the Corporation. Mr. Moffett states that the nuisances complained of with regard to noise, &c., could be removed at a trifling cost. The Tramways Co. is to be requested to carry out the suggested alterations.

TORQUAY: *Public Lighting.*—The Surveyor has prepared a report on the cost of public electric lighting in various towns, which has been printed and circulated amongst the members of the Electric Lighting Committee. The Works and Highways Committee, who have had this matter in hand, recommend that the Electric Lighting Committee should be recommended to grant a reduction in the present charge for public lighting.

URUGUAY: *Telephonic Communication.*—The *Review of the River Plate* states that the Uruguayan Government intends to spend £20,000 on a telephone system for the police stations throughout the Republic. Mr. A. Bennett has arrived from England, under his agreement with the Uruguayan Government, for establishing an automatic telephone service in Montevideo.

WATFORD: *Euston-Watford Electric Railway.*—The London & North Western Railway Co. have informed the Council that work upon the new electric railway from Euston to Watford is about to be commenced, but that no date can be given for its completion.

WEST HAM: *Writ Served on Council.*—The India Rubber, Gutta Percha & Telegraph Works Co., Ltd., presumably as ratepayers, have issued a writ to restrain the Corporation from paying interest on an overdraft from the bank in connection with the electricity undertaking. The sum in question has not been sanctioned by the Local Government Board, and the Company claim that the payment of the interest upon it is illegal.

WESTON-SUPER-MARE: *Condition of Tramway Track.*—Representations are to be made to the Board of Trade concerning the condition of the tramway track, which is alleged to be a nuisance and a source of danger to the ordinary traffic.

WOLVERHAMPTON: *Tramway Intercommunication Abandoned.*—For nearly two years the overhead trolley cars of the Wolverhampton & District Tramways Co. have been running over certain of the lines of the surface-contact lines in the borough. The company, however, has stated its intention of abandoning the arrangement next year for the reasons given below. It is pointed out that the through service from Dudley to Wolverhampton has been a loss to the company. The additional weight (nearly one ton) thrown on the cars by the addition of the skate has increased the consumption of current by 0·30 of a unit per car mile, and the constant repairs necessary for the skate equipment have further increased the expenses, due somewhat to having to fit such equipment to trucks which were not originally designed for the purpose. Further, the fact is that revenues have not in the least improved by the arrangement. The company state they have taken time and much pains to try and overcome the losses, but the position after nearly two years does not improve. They do not know how far the Corporation would again allow them to offer the suggestion as to the equipment of the line from the Fighting Cocks to Snow Hill on the overhead system, but this would be the means of enabling the company to satisfactorily continue the through

Digitized by Google

services. Failing this, the company ask the Corporation to allow the through services from Dudley to be discontinued. As a result, notice is given that the intercommunication between Wolverhampton and Dudley will cease on January 10th next unless a satisfactory arrangement can be entered into.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

AUSTRALIA: *Sydney.*—Tenders are invited on behalf of the Sydney Municipal Council by Messrs. Preece & Cardew for five water-tube boilers each capable of evaporating 24,000 lbs. of water per hour; also economisers, mechanical stokers, feed-pumps, pipe-work, &c. Particulars from Messrs. Preece & Cardew, 8 Queen Anne's Gate, Westminster, fee £1 1s. returnable; and tenders to the Town Clerk, Town Hall, Sydney, N.S.W., by February 22nd, 1909.

BEDFORD.—The Finance Committee are in negotiation with several companies with a view to obtaining a loan of £10,000 for electric lighting purposes.

BLACKPOOL.—Tenders are invited for the supply of coal to the electricity department during 1909. Particulars from the Borough Electrical Engineer, and tenders by December 22nd.

CLACTON.—Tenders will shortly be invited for a crane for the electricity works.

DOVER.—A Local Government Board inquiry will be held to-morrow into an application for sanction to borrow £4,600 for electrical extensions.

ECCLES.—The Local Government Board has sanctioned the borrowing of the following sums :—£4,091 for new machinery, £2,000 for mains, £800 for transformers, £1,200 for house services, and £500 for motors on hire. Sanction has also been received to the borrowing of £4,150 excess expenditure.

GLASGOW.—The Secretary for Scotland has granted leave for the borrowing of £150,000 for extensions to the electrical undertaking.

KEIGHLEY.—An application is to be made to the Local Government Board for sanction to borrow £12,820 for electric lighting purposes.

LEYTON.—A Local Government Board inquiry was held last week into an application by the Council to borrow £1,299 for electric lighting purposes. This sum is required for new mains.

LONDON: *Battersea.*—Tenders are invited for the supply of coal for the Electricity Department during 1909. Particulars from the Electrical Engineer, and tenders to the Town Clerk by December 22nd.

Hackney.—A loan of £3,290 for mains extensions, repayable in 30 years, has been sanctioned by the Finance Committee of the London County Council.

RADCLIFFE.—The Local Government Board inquiry referred to in our issue of November 19th in connection with the Council's application for sanction to borrow £14,500 for electrical extensions, was continued on Wednesday last week. Opposition was offered by several large firms in the district and by the Lancashire Electric Power Co., it being contended that the power company was in a position to supply current at cheaper rates than the Council could generate it.

SOFIA.—A scheme for lighting the harbour by electricity is to be formulated.

WIGAN.—Tenders are invited for the supply of cables and electrical accessories during the coming year. Particulars from the Electrical Engineer, and tenders to the Town Clerk by December 21st.

Miscellaneous

AUSTRALIA.—The Board of Trade correspondent at Melbourne (Mr. M. Hirsch) has forwarded a copy of the conditions and specifications relating to the supply, delivery and erection, at the Post Office, William Street, Sydney, of a branching metallic multiple magnetic switchboard. Tenders will be received by the Deputy Postmaster-General at Sydney up to 2.30 p.m. on April 28th, 1909. The conditions may be obtained at the Commonwealth Offices in London, and copies may be seen by British makers at the Commercial Intelligence Branch of the Board of Trade.

LEEDS.—The Tramways and Electricity Committee invite tenders for the insurance of their third-party risks in connection with the tramways undertaking. Particulars from the General Manager, and tenders to the Town Clerk by January 4th.

MANCHESTER.—Tenders are invited for an installation of electric bells and telephones at the Bradford Baths. Particulars from the Town Clerk, and tenders by December 23rd.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

N.W.—Alterations and additions, Seto Works, Mead's Road, Little Stanmore, Hendon, for R. E. Thomas.

YARMOUTH: *Tramway Extension.*—As the cost of extending the tramway service on the South Denes is estimated at £2,000, the Corporation has decided not to carry out this extension, owing to the small amount of traffic which is likely to be attracted by it.

Buildings, corner of High Street, Camden Town and Kentish Town Road. Architect, D. Joseph, 73 Basinghall Street, E.C.

Lodge Building, Lower William Street, Regent's Park. Architect, F. M. Elgood, 98 Wimpole Street, W.

S.W.—Police station and quarters, Battersea. Architect, J. Dixon Butler, New Scotland Yard, S.W.

Alterations and additions at Blenheim Club, King Street, St. James's. Architect G. A. Lansdown, 9 Regent Street, S.W.

S.E.—Factory, Somer's Place, Lambeth, for the Trustees of the Stockwell Orphanage.

Re-building, Joiners' Arms Public House, Church Street, Deptford. Architects, Wylson and Long, 16 King William Street, E.C.

Re-building "High Cliff," Wellington Grove, Greenwich, in connection with Ursuline Convent. Builder, W. Nash, Childers Street, Deptford.

W.—Development of Park Royal Estate, North Acton. Solicitors, Redfern and Hunt, 13-14 Abchurch Lane, E.C.

Additions to Aylesbury Dairy Co.'s premises, St. Petersburgh Place. Architect, W. J. Keith, 7 East India Avenue, E.C.

W.C.—Alterations to laboratories at 17 Bloomsbury Square (£647). Architect, G. A. Lansdown, 9 Regent Street, S.W.

Building, Tottenham Court Road, for Central Young Men's Christian Association. Architect, R. Plumbe, 13 Fitzroy Square, W.

PROVINCES.

ABERBORGOED (MON.).—County School. Architect, J. Bain, Arcade Chambers, High Street, Newport, Mon.

ABERDARE.—Receiving Home. Architect, T. Roderick, Aberdare.

BARNET (HERTS).—Extension of girls' grammar school (£4,300). Architect, J. Ladds, 93 Pemberton Road, Harringay, N.

BOOTLE.—Workmen's dwelling (£7,100). B. J. Wolfenden, Engineer and Surveyor, Town Council.

CAMBRIDGE.—Agricultural college. Architect, Arnold Mitchell, 17 Hanover Square, W; builders, Messrs. Pringle, of Cambridge.

School (£15,000). Surveyor, — Julian, Town Council.

CARDIFF.—Extensions at Roath, abattoirs and meat market. W. Harper, City Engineer, Town Hall.

CHESTER.—Proposed secondary school. Reginald Potts, Clerk to Cheshire County Council, Chester.

COLCHESTER.—Co-operative stores and premises. Architects, Goodey & Cressall, High Street.

DEVONPORT.—Church. Architect, G. H. F. Prynne, 6 Queen Anne's Gate, S.W.

FOLKESTONE (Kent).—Library. A. E. Nicholls, Borough Surveyor, Folkestone.

GREAT YARMOUTH.—Addition, hospital. Architects, Olley & Howard, Queen Street.

Additions, infirmary. Architect, H. Arnott, High Street, Gorleston-on-Sea.

MANCHESTER.—Tenders are invited for the wiring and fitting for electric lighting of the Bradford Baths. Particulars from the Town Clerk, and tenders by December 23rd.

MARDY (Glamorganshire).—Additional pavilion at Mardy Isolation Hospital, Merthyr Tydfil (£3,370). T. F. Harvey, Borough Engineer, Merthyr.

NEATH (Glamorgan).—Bank for Metropolitan Bank of England and Wales. Architect, J. Moxham, Castle Street, Swansea.

NORTHAMPTON.—Hippodrome. Architect, Bertie Crewe, 75 Shaftesbury Avenue, W.C.

NORWICH.—New offices for Guardians. Architects, Morgan & Buckingham, 1 Upper King Street, Norwich.

PETERBOROUGH.—Church Institute. Architect, S. Dodson, Peterborough.

Fire station. Architect, F. J. Gill, 236 Rolfe Street, Smethwick, Birmingham.

School, Fletton. Architect, H. Leete, Huntingdon.

PORTSMOUTH.—Workmen's dwellings. P. Murch, Engineer and Surveyor, Town Council.

SUTTON.—Additions to buildings of Sutton Co-operative Society.

WALSALL.—Rolling mill and chimney stack, Green Lane, Birchills, for the Talbot Stead Tube Co., Ltd.

Alterations and extensions to works, Bloxwick, for the New Delaville Spelter Co., Ltd.

WIGAN.—Fifty houses for tramway men (£11,100). Wm. Balton, surveyor, Town Council.

WINTON (BOURNEMOUTH).—School, Brassey Road. Surveyor, Frederick Wm. Lacey, Bournemouth County Borough Council.

WOKING.—Technical school. Architects, Jarvis & Richards, Queen Anne's Gate, S.W.

Digitized by Google

TENDERS RECEIVED AND ACCEPTED

ARGENTINE.—A concession has been granted to Señores Gandulfo and Diaz Valdez for the construction of an electric tramway in the town of Buenos Aires. Plans must be presented within six months, and within three months of the date of approval work must be begun. The whole work is to be completed within two years.

BOURNEMOUTH.—The tender of Messrs. W. Cory & Sons for the supply of Welsh smokeless coal for the tramways power house during the coming year has been accepted at 17s. 5d. per ton.

CARDIFF.—The Electrical Engineer has been authorised to purchase from Mr. A. G. Brown, of Manchester, at £80, a vacuum and pressure dry insulating machine, varnish tank and pump, for use in connection with the re-insulation of armatures and field coils. Two patent rail grinders fitted with carborundum blocks are to be purchased from the National Rail & Tramway Appliance Co., Ltd., Liverpool, at £25 each.

CLACTON.—The tender of Messrs. Elliott Bros. for two ammeters has been accepted at £18 16s. 6d.

DERBY.—The Electric Lighting Committee has accepted the tender of the Derby Coal Co. for the supply of 1,000 tons of coal for the electricity department. The tender of the Lea Recorder Co. for a second water recorder at £46 10s. has also been accepted.

LONDON: *London County Council.*—The following tenders have been received, for the roadwork and platelaying, exclusive of the supply of rails and special trackwork, in connection with the reconstruction, on the underground conduit system of electric traction, of the existing tramways from Hackney Road, *via* Mare Street, and Lower and Upper Clapton Roads, to Stamford Hill, and the construction on the same system of traction of the authorised tramway in Amhurst Road and Dalston Lane. The tenders also contain provision for the execution of certain paving works outside the tramway tracks in connection with the widenings along the route:—Dick, Kerr & Co. (recommended), £82,715; W. Manders, £84,333; A. M. Coles, £84,555; J. Mowlem & Co., £88,664. The chief engineer's estimates, comparable with the tenders, are £84,090 for tramway works, and £3,887 for paving works, or a total of £87,977. Provisional sums, amounting to £15,700, are included in each of the tenders for alterations of pipes, mains, &c., the cost of which works cannot be more accurately estimated beforehand, and a sum of £5,000 is also included for any other contingencies which may arise. The tender of Messrs. Dick, Kerr & Co., Ltd., is recommended. Messrs. Dick, Kerr & Co., Ltd., are to be allowed to sub-let to the undermentioned firms the following portions of the work:—(1) to the Anderston Foundry Co., Ltd., or Wilsons Pease & Co., Ltd., the yokes; (2) to Doulton & Co., Ltd., or Buller's, Ltd., the insulators; (3) to Bayliss, Jones & Bayliss, or Guest, Keen & Nettlefold, Ltd., the tiebars, bolts, &c.; (4) to the Associated Portland Cement Manufacturers, Ltd., the cement; (5) to Harrison & Co. (Lincoln), Ltd., and Hadfield's Steel Foundry Co., Ltd., the plough boxes and drain boxes; and (6) to the Forest City Electric Co., Ltd., the bonds.

London County Council.—The Fire Brigade Committee report that certain alterations will be necessary in the Post Office telephone arrangements at the chief station of the fire brigade as the result of the reconstruction, now being carried out, of the engine-house block. There are in the existing watch-room a cabinet with which all the telephone lines to other stations, &c., are connected, and an inter-departmental board with which certain lines to various parts of the building are connected. The inter-departmental board and the telephone lines connected therewith will be abolished, and it is proposed to have fixed in the new watch-room a new cabinet (in place of the existing cabinet) to which all the telephones and fire-signal apparatus at present on the existing cabinet will be transferred, and to provide in connection with this new cabinet 10 additional extensions (to the stables, dynamo-room, duty-room, and various other rooms and offices in the station), most of which are rendered necessary by the abolition of the inter-departmental board. The annual charge, under a new 10 years' lease, for the new cabinet and extensions will be £52 7s. 6d., and the annual charges of £31 7s. 6d. and £34 respectively now paid for the existing cabinet and the inter-departmental board will cease. The effect of the alterations will consequently be a net reduction of £14 a year, and it is recommended that this arrangement be entered into with the Post Office.

The Main Drainage Committee, having dispensed with the electric battery in use at the Crossness outfall works, and entered into an agreement with the Erith Urban District Council for the supply of electricity required at the works, the following offers have been received for the purchase and removal of the battery: Mr. E. J. Webster, Stratford, E. (recommended), £205; Hart Accumulator Co., Ltd., Stratford, E. (£7 10s. a ton, about), £200; Premier Accumulator Co., Ltd., Northampton, £150; Electrical Power Storage Co., Ltd., Great Winchester Street, £110.

London County Council.—The Fire Brigade Committee of the Council have received the following tenders for the electric lighting of the Camden Town fire station, which is at present lighted by gas: Tredegar & Co., 56 Victoria Street, S.W. (recommended), £166 10s.; Nursey & Marr, 53 Victoria Street, S.W., £175; W. J. Fryer & Co., Bravington Road Works, Paddington, W., £193; Chas. Pullan, 51 and 52 King's Arcade, Bradford, and 68A Lincoln's Inn Fields, W.C., £235; W. Leonard & Co., 4 Soho Street, Oxford Street, W., £275.

Bermondsey.—The Council have accepted the quotation of Johnson & Phillips, Ltd., at £7 1s. 6d., less 2½ per cent., for the supply of 110 yards 7/22 twin lead-covered armoured cable, also the tender of the British Electric Calibrated Fuse Co., at £9 3s. 10d., for six switchboard fuses.

Stepney.—For the supply and delivery of a quantity of rubber cable, the Council has received the following tenders:—Baxter & Caunter, £87 6s. 6d. (accepted); W. T. Henley's Telegraph Works Co., Ltd., £106 17s. 8d.; W. T. Glover & Co., Ltd., £106 17s. 8d.; The India Rubber Gutta Percha & Telegraph Works Co., £106 17s. 7d.

Wandsworth.—The Council have accepted the tender of H. J. Whitehead, at £14 15s., to carry out certain works required to the electric installation at the Wandsworth Town Hall.

LUTON.—The tender of the Hudson Economiser Co. for the erection of a cooling tower of 100,000 gallons capacity per hour, at £556, has been accepted, and that of the Sheepbridge Coal & Iron Co. for iron piping, at £137 15s.

SUNDERLAND.—The following tenders have been accepted:—Lead-sheathed E.H.T. cable, India Rubber, Gutta Percha & Telegraph Works Co., Ltd.; cable racks, Messrs. Doulton & Co.

COMPANIES' MEETINGS AND REPORTS

BLACKPOOL, ST. ANNE'S & LYTHAM TRAMWAYS CO.—At the annual meeting on Thursday the report and accounts given in our last issue were adopted. The fact that the traffic receipts during the year were less by £370 was attributed by the Chairman to the bad weather and to the counter attractions in London, such as the Franco-British Exhibition. The sinking fund, he said, was being put aside for paying off prior debentures, and it now stood at £6,000. The conversion of the share and debentures of the Blackpool Electric Tramways (South) Co. into share and debentures of the present Company was being proceeded with in accordance with the resolutions on the subject, and the trustees for the debenture holders had approved of the payment of 2½ per cent. on account of arrears of interest on debenture stock.

DORMAN, LONG & CO.—At the annual general meeting last week, the report and accounts, given in our issue for November 19th, were adopted. The chairman, Mr. A. J. Dorman, in his speech, mentioned that the new electrically-driven rolling mill was at work, and, so far as they could see at present, it promised to be a great success. The electrically-driven cogging mill was expected to be in operation during February. When all this plant was in working order the works, he said, would be capable of turning out a large additional quantity of steel at a low cost.

INDIA RUBBER, GUTTA PERCHA, & TELEGRAPH WORKS CO.—At the annual meeting on Monday, the report and accounts given in our last issue were adopted. Major Leonard Darwin, who presided, stated that the general turn-over during the year had considerably increased, although in some branches of the business there had been a falling off.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON.—The report for the year ended September 30th states that since the date of the last report the scheme for the conversion of the profit-sharing secured notes and for raising further money by means of prior lien bonds, which was duly sanctioned by the Court, has been carried into effect, and the voluntary liquidation which was necessary to carry the scheme under the Joint Stock Companies Arrangement Act, 1870, was closed under order of Court on July 21st, 1908. Since the date of the balance-sheet the loan of £183,175 to the Metropolitan District Railway Co. has been repaid, and the sum of £64,998 appearing in the balance-sheet has been paid to the trustees of the power house depreciation fund. Half-yearly accounts will, in future, be submitted to the shareholders, made up to June 30th and December 31st in each year. It is proposed to hold half-yearly meetings, and at the meeting to be held next February there will be submitted a balance-sheet made up to the 31st inst., with a revenue account of the company from the close of the liquidation to the end of the year. The meeting to be held on the 21st inst. has only been convened in order to comply with the provisions of the Companies' Acts, which, in effect, require a company to hold one ordinary general meeting in each year. The business to be transacted will, therefore, be of a purely formal nature.

P. & O. Batti Wallahs' Society.—(Birmingham Local Section.)—Meetings are held at 7.30 p.m. on the last Thursday in each month at Prince's Café, Corporation Street, Birmingham. It is hoped that every member will endeavour to attend these meetings regularly throughout the winter season.

Digitized by Google

MISCELLANEOUS CITY NOTES

ANGLO-ARGENTINE TRAMWAYS CO.—The directors have declared a final dividend of 5s. per share for the year to December 31st upon the second non-cumulative preference shares. A final dividend of 3s. for the same period has also been declared on the cumulative first preference shares, being at the rate of 6 per cent. per annum. Both dividends are less tax.

BRITISH COLUMBIA ELECTRIC RAILWAY CO.—Subscriptions have been invited this week for an issue of £500,000 4½ per cent. perpetual consolidated debenture stock. This stock is perpetual and irredeemable, and is entitled to the benefits of a trust deed dated February 23rd, 1907, in favour of the British Empire Trust Co., Ltd., whereby the whole of the company's assets and undertaking, including its uncalled capital, are charged by way of first floating charge according to English law, subject to the existing mortgages and charges created to secure £233,200 first mortgage debenture and £212,600 Vancouver power debentures. The properties of the company include over 65 miles of electric railway, and 14 miles which are being operated under agreement with the Canadian Pacific Railway Co. On September 30th, 1908, the number of 8-c.p. lamps connected to the electric lighting system was 310,866, in addition to 9,759 h.p of motors. The proceeds of the present issue are required for the general purposes of the company, and more particularly in connection with the further increase of the water-power electric plant at Lake Buntzen, and additional electric railways.

BRITISH INSULATED & HELSBY CABLES.—The transfer books will be closed from the 18th to the 31st inst., both days inclusive, for the preparation of warrants for interest on the debenture stock of this company. The warrants will be posted on the 31st inst.

EASTERN TELEGRAPH CO.—A dividend of 3½ per cent. per annum, less tax, on the preference shares for the quarter ending December 31st, 1908, and a third quarterly dividend of 1¼ per cent. on the ordinary shares, free of tax, in respect of profits for the year 1908, has been announced.

EASTERN EXTENSION, AUSTRALASIA & CHINA TELEGRAPH CO.—An interim dividend for the quarter ended September 30th of 2s. 6d. per share free of tax has been announced.

GATESHEAD & DISTRICT TRAMWAYS CO.—Parr's Bank, Ltd., has been authorised to receive applications for the purchase of £10 shares at £8 15s. per share of this company, ranking for a full year's dividend at the next meeting.

GLOBE TELEGRAPH & TRUST CO.—A quarterly dividend of 2s. per share has been declared upon the ordinary shares.

GREAT NORTHERN TELEGRAPH CO.—An interim dividend of 5s. per share, less income tax, has been declared.

MEXICAN LIGHT & POWER CO.—The directors have authorised the statement, for the information of the shareholders, that although they are opposed to a lease of the company to the Mexico Tramways Co., as set out in our last issue, they are agreeable to an amalgamation as an alternative.

NATIONAL TELEPHONE CO.—The transfer books of three-and-a-half per cent. and four per cent. debenture stocks will be closed from December 18th to December 31st, inclusive, for the preparation of the warrants for the interest due January 1st.

NORTH MELBOURNE ELECTRIC TRAMWAYS & LIGHTING CO.—A meeting of the debenture holders will be held to-morrow to consider the following resolutions: (1) That the security shall not become enforceable nor the principal become payable solely on account of the interest being in arrear during any part of the period from November 30th, 1908, up to and including December 1st, 1913; and (2) that the moneys paid by J. G. White & Co., Ltd., under their guarantee of debenture interest, due December 1st, 1908, may be applied for the general purposes of the company.

UNITED RIVER PLATE TELEPHONE CO.—An interim dividend of 6 per cent., free of tax, upon the ordinary shares has been announced.

WESTERN TELEGRAPH CO.—The directors have declared the first quarterly interim dividend of three shillings per share, free of income tax, for the year ending June 30th, 1908, being at the rate of 6 per cent. per annum. The transfer books will be closed from December 14th to 19th, both days inclusive, and the dividend will be payable on the 21st inst.

Dissipation of Fog by Electricity.—The Works Committee of the Westminster City Council has received a letter from Mr. E. L. Walford, 47 Hamilton Terrace, N.W., stating that he proposes to form a small syndicate to try on a practical scale Sir Oliver Lodge's system of dissipating fog by means of electricity. He asked for permission to try the experiment in Westminster upon land the property of the Council. The Works Committee have agreed (subject to the usual sanction) to allow Mr. Walford to experiment on a portion of the Grosvenor Canal property, provided the experiment can be conveniently carried out without detriment to the Council's work and without danger.

APPOINTMENTS AND PERSONAL NOTES

Eighty-eight applications were received by the Stoke Newington Borough Council for the post of engine-driver for the new electricity engine-house. Mr. Alexander Turnbull has been appointed to the post.

The salary of Mr. Lloyd Jones, station superintendent at West Ham, has been increased from £280 to £300 per annum.

Applications are invited for the post of secretary to the Institution of Electrical Engineers. (See an advertisement this week.)

The Rawtenstall Corporation require a Borough Electrical and Tramways Engineer at a salary of £200 per annum. Applications to the Town Clerk by December 23rd.

Tenders applications have been received by the Erith Urban District Council for the dual position of electrical engineer and tramways manager. Two officers are at present engaged in the respective departments, but it has been decided on the ground of economy to dispense with the services of one of them. The applications include the present tramway manager and the present electrical engineer, in addition to Mr. J. D. Pember, electrical engineer to the Dartford Urban District Council, and Mr. W. A. Tester, electrical engineer and tramways manager to the Lancaster Corporation.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £65 10s. to £66 per ton (last week, £65 to £65 10s. per ton).

CHANGE OF ADDRESS.—On and after the 21st inst. the London offices of Messrs. Stewarts & Lloyds, Ltd., will be removed to Winchester House, Old Broad Street, E.C.

BANKRUPTCIES.—A petition for the winding-up of the Aluminium Corporation, Ltd., will be heard on January 12th, 1909, before Mr. Justice Swinfen Eady, and persons desiring to appear are requested to communicate with Mr. Elvy Robb, 79-83 Temple Chambers, London, E.C.

A meeting of the Private Telephone Co. (old company) will be held at 27 Chancery Lane, London, on Wednesday, January 20th, at 12.30 p.m., to receive the liquidator's report of the winding up.

CHRISTMAS HOLIDAYS.—The offices, works, and stores of the Union Electric Co., Park Street, Southwark, will be closed from December 25th to 29th.

MESSRS. BRUCE PEEBLES & CO.—This company has been successfully reconstructed, and is actively engaged in the manufacture of all the different classes of electrical machinery with which its name has for so long been associated. The business has been conducted without interruption, and as its control is now in the hands of an entirely new and influential board of directors, it is believed that the success of the business is assured. The new board consists of the following gentlemen: Messrs. A. W. Tait, M. B, Mountain, C. J. Shiells, Alex. Mackenzie, Chas. H. M'Euen, F. E. Andrews. The company owns the sole manufacturing rights in Great Britain and the Colonies of the well-known La Cour Motor Converter.

"GRAL" LAMPS.—We are informed that since the announcement of the reduction in price of "Gral" metal filament lamps, the Armorduct Manufacturing Co., Ltd. (Farringdon Avenue, E.C.) have been working at considerable pressure in filling orders for these lamps. Arrangements have been made for a much larger supply shortly, which will enable good stocks to be kept. The 100–135-volt lamps are made in sizes of 20–30, 50, and 100 c.p., and the 200–265-volt lamps in 40–50 and 100 c.p. An efficiency of 1 watt or slightly more per Hefner candle-power is claimed. Lists will be sent to any of our readers on application to the firm.

Institution of Electrical Engineers.—At the meeting of the Institution of Electrical Engineers on January 14th, a Paper will be read by Mr. Stanley Clegg, Electrical Engineer and Tramways Manager to the Lincoln Corporation, upon "The G.B. System from a Tramway Manager's Point of View."

The Proposed Tax on Electricity in Germany.—The Paper which was read by G. Dettmar, the Secretary of the Verband Deutscher Elektrotechniker, at the special meeting on November 24th of the Elektrotechnische Verein in Berlin, on the proposals of the German Government relating to the taxation of electricity, has just been published, together with the ensuing discussion, in the *Elektrotechnische Zeitschrift*. The author showed that the Government had considerably over-estimated the probable gross revenue from the proposed tax, and had also under-estimated the costs of administration, with the result the net revenue would fall very short of what was expected. He also considered in detail the effect of the tax on the industries of the country, and concluded with a formidable list of telling objections to the imposition of the tax. A long discussion followed the Paper, in which most of the speakers strongly condemned the tax.

"Electrical Engineering," although the Cheapest Electrical Paper (Price 1d. weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

An account is given of the proceedings at a Local Government Board inquiry before Mr. Hooper, at which the Lancashire Electric Power Co. opposed the application of the Radcliffe Urban District Council for sanction to raise a loan to extend the Council's works. The power company, who were supported by a number of local manufacturing firms, contended that the Council would find it more economical to buy energy in bulk from the company's station at Radcliffe, and they also complained of the difficulties the Council had placed in the way of the company obtaining power consumers in this district, although the Council's own works were on too small a scale to supply large power consumers. It was elicited that both the Radcliffe and the Farnworth District Councils made the company pay them 2½ per cent. on the gross revenue derived from consumers supplied by the company in these areas. (Page 804.)

The new generating station of the North Metropolitan Electric Power Supply Company at St. Albans is of particular interest, as it depends entirely on refuse for fuel. A continuous-current supply at 2 × 230 volts is given in the town of St. Albans, but by an ingenious arrangement of compensators supplied from slip-rings connected to the generator armatures, two further constant potential points are obtained, and a five-wire supply at 4 × 115 volts will be given to a neighbouring factory which has at present a private 115-volt lighting and power system. As the total voltage of the main generators is thus only about 460 volts, it is raised to the station pressure of 470 to 480 volts by means of boosters. The booster sets can be used for boosting either for battery charging or discharging, or for the above purpose. When the main generators are not running, one booster set is used as a motor generator driven from the battery for supplying the above-mentioned factory. Only two generating sets, with a capacity of 150 kw. each, are installed at present. The engines are run non-condensing. (Page 805.)

In the discussion on Mr. J. W. Beauchamp's Paper on "Plans and Records for Electrical Distributio

Digitized by Google

Systems," by the Leeds Local Section of the Institution of Electrical Engineers last week, several mains engineers and others gave particulars of their practice in this respect, and all the speakers agreed as to the importance of an accurate but not too elaborate system of mains recording. (Page 809.)

The Paper on "The Production of Nitric Acid by the Electric Discharge" by Messrs. W. Cramp and B. Hoyle, discussed last Thursday at the London meeting of the Institution of Electrical Engineers, and also before the Manchester Local Section of the Institution on the preceding Tuesday, commenced with a brief review of the methods for the "fixation" of the nitrogen of the air by previous experimenters, followed by a very clear account of the different forms which the alternating discharge in air can assume. The main part of the Paper contains full particulars of the results of a long series of experiments with a simple form of apparatus, undertaken to trace the influence of certain variables on the efficiency of the nitrogen fixation process, and finally the authors gave the theoretical conclusions drawn from their researches, and indicated the direction in which sufficiently improved results might be expected to enable electrically-produced nitrate to compete commercially with cyanamide for fertilising purposes. Only a few speakers took part in the London discussion. Mr. W. Duddell asked for some fuller information on certain points connected with the nature of the discharge, and one or two speakers mentioned processes as being omitted from the Paper, but did not advance much in the way of particulars. Mr. Cramp, in his reply, dealt satisfactorily with practically every point raised. The discussion at Manchester chiefly turned upon the physical side of the subject. (Page 810.)

A new form of liquid motor-starter is described in a short article. (Page 815.)

The effect of a new form of flame arc lamp is shown by a photograph taken of an actual installation. (Page 816.)

A Paper was read recently by Mr. S. R. Gibbon on "Electrical Heating and Cooking Apparatus," before the Liverpool and District Electrical Association, in which the features of the systems of construction of the leading designs of heating and cooking apparatus at present on the market were briefly described. (Page 816.)

In a Paper read before the Birmingham Local Section of the Institution of Electrical Engineers, Dr. J. D. Coales described a method of artificially saturating the iron of transformers by direct-current, so that when an alternating E.M.F. is applied to one of the windings, the magnetisation varies in a cycle high up on the saturation curve. The use of this arrangement in the testing of alternators on inductive loads with transformers instead of choking coils was explained, and comparative test results by the two methods were given. In the discussion on the Paper, the convenience of the method was emphasised, and the opinion was expressed that the possibility of excessive heating of the transformers due to the extra core losses was not of importance. (Page 817.)

A written communication to the discussion on the Paper dealing with generalisations in the design of electrical machinery, by Messrs. J. C. Macfarlane and H. Burge, has been received from Dr. R. Pohl, of the Phœnix Dynamo Manufacturing Co., of Bradford. While admiring much of the authors' work, Dr. Pohl does not agree with their conclusion that for the best economy the cost of the active material in the armature and magnetic circuits should be equal. (Page 819.)

Experiments with high candle-power Osram lamps for public lighting are being made in Birkdale.—Further conferences are being held by the West London local authorities concerning the condition of the track of the London United Tramways. It is suggested that Sir Clifton Robinson should personally inspect the track complained of with the respective borough surveyors.—The sum of £500 damages has been awarded against the Dublin United Tramways Co. in relation to an accident caused by a rut alongside the track.—Owing to the local opposition, the London County Council does not propose to promote the suggested tramway down Sutherland Avenue.—As the Middlesbrough Corporation and the local tramway company cannot come to terms concerning tramway extensions, it is suggested that the adoption of the trackless trolley system will solve the difficulty.—The Tramways Committee of the Wolverhampton Corporation have acquiesced in the suggestion of the tramway company that through running should be abandoned, and acknowledge the effort of the company to make this successful. (Page 819.)

The Fareham Council require three alternators and accessories, and the Leith Corporation a 600-kw. generator. Local Government Board inquiries have been or will be held as follows: Cleethorpes (£4,000); Epsom (£1,500). Loans have been sanctioned, for electrical extensions, as follows: Wednesbury (£600); Frome (£11,000); Marylebone (£4,426); Battersea (£2,868); Woolwich (£753). A new motor-generator will shortly be required at Southampton; electricity meters are required at Beckenham; overhead tramway material at Portsmouth, and arc lamps and posts at Middlesbrough. The London County Council has accepted an offer by Messrs. J. Cochrane & Sons to provide condensing water pipes at the Greenwich power-house at an estimated cost of £8,000. (Page 820.)

A scheme of rearrangement of the capital of the Anglo-Argentine Tramways Co. has been sanctioned by the shareholders, as also has a considerable increase of the capital of the United Electric Tramways Co. of Montevideo. At the annual meeting of the Shanghai Electric Construction Co. on Friday, it was stated that there are several matters in dispute between the company and the municipality. Sir Edgar Speyer stated at the annual meeting of the Underground Electric Railway Co. of London on Monday that the traffic on the District Railway and on all the tubes showed satisfactory increases. In future, half-yearly balance sheets will be prepared to June 30th and December 31st. Subscriptions have been invited to an issue of £100,000 5 per cent. first mortgage debenture stock by the South London Electric Supply Corporation. (Page 822.)

The specification for the "Davy" automatic switch for use with small auto-transformers supplying metal filament lamps has been published. Among the other specifications which were published on Thursday by the Patent Office, is one by J. Johnson for a hard insulating material composed of sulphur, mica, and lamp-black, and another for an induction motor with a double rotor by Crompton & Co., Ltd., J. C. Macfarlane, and H. Burge. In this machine a high-resistance rotor is used when starting up, and a low resistance rotor when running. Three specifications by C. Ruzicka relate to the composition of insulating material of high specific resistance for heating and cooking apparatus. An ingenious form of self-starting mercury vapour lamp, in which the mercury is forced out of the illuminating portion of the quartz tube by the pressure of the vapour, is described in a specification by H. A. Kent, H. G. Lacell, and the Silica Syndicate, and Messrs. Siemens Brothers' Dynamo Works, Ltd. and O. Kieffer have one for a method of ventilating the rotors of turbo-alternators by forcing air through passages in the rotor teeth. An application for the amendment of a specification relating to mariners' compasses has been made by the executors of the late Lord Kelvin, and H. Mosey wishes to entirely reword the

Digitized by Google

claims in a specification for a gravity-fed arc-lamp with converging carbons. Short abstracts of the above specifications are given in our Patent Record. (Page 825.)

A Local Government Board inquiry, recently held at Radcliffe, a report of which appears on another page, brings into prominence a practice in connection with the supply of electric power that cannot be too seriously discouraged. There are cases in which certain portions of a power company's authorised area in which local authorities have their own electricity works are marked out, as it were, as the local authorities' own preserves. The power company is not debarred from supplying consumers in that area, but it must in the first instance obtain the consent of the local authority. Instances of such consent are now becoming fairly frequent, when, for instance, the power consumer is at the outskirts of an area and is more accessible to the company than from the local electricity works, or when the municipal works are built on too small a scale to deal with consumers requiring heavy power loads. There is a growing practice, however, of charging the power company a price for the local authority's consent, a practice certainly not contemplated when the power companies acts were passed by Parliament. It was elicited during the Local Government Board inquiry at Radcliffe that 2½ per cent. of the gross revenue from the power company's consumer in the local authority's area had to be handed over to the District Council. In Farnworth the same condition obtains, and in Salford and Bury a nominal fee is exacted. The theory that a consent which may be withheld by a local authority has to be bought, has done so much harm in the tramway industry that a vigorous protest must be made against its being adopted in the electric power industry. If a local authority is unable to supply a consumer itself, it is obviously to the benefit not only of the consumer and the power company, but also to the community at large, that free facilities should be given to the company which can step in and supply the demand.

The Paper by Messrs. Cramp and Hoyle, which has been discussed by London and Manchester meetings of the Institution of Electrical Engineers, described a valuable series of experimental researches in the domains of both physics and chemistry. Possibly, from an electrical engineering point of view, however, the subjects dealt with may influence the future rather than the present. From the nature of the matters treated, it is possible that these researches might have been better brought to the notice of those specially competent to discuss the subject, by the Paper being read before some more specialised body, such as the Faraday Society; yet doubtless wider publicity will be given to the authors' work through the Institution of Electrical Engineers, and, indeed, the rapidity with which electrochemistry is merging into electrical engineering quite justifies the choice of an engineering institution as the medium of publication. From a strictly industrial point of view, perhaps, the net result of the researches may be a little disappointing, for the Paper almost leaves an impression that, notwithstanding their vast amount of work, the authors have failed to prove any commercial superiority of their method of utilising electrical discharges for producing nitrogenous compounds over the cyanamide process. Incidentally, however, the experimenters have done a most interesting and valuable piece of work from the electro-physical point of view, apart from its relation to industrial chemistry, in distinguishing between the various forms taken by the high-tension discharge, and in defining the conditions under which they occur, work which cannot fail to bear ultimate fruit in other branches of electrical engineering.

Most electrical engineers have, at some period of their career, passed through that interesting and essential, yet often somewhat neglected, department of an engineering works, whether small or large, the test-room. Indeed, for those who do not in later years take up the management of electrical machinery, either in a generating station or other works, the surmounting of the practical difficulties met in the testing of all classes of electrical apparatus during this period is one of the most valuable parts of the engineer's training on the technical side. It is then that he becomes familiar with many of the little peculiarities and ills of electrical machinery, and becomes as expert and quick in his diagnosis as a practised physician. One of the chief difficulties confronting the engineer in the test-room is the lack of auxiliary apparatus, and any little devices or "kinks," whereby he is enabled to carry out tests, without the use of special apparatus and with a low consumption of energy, are always welcome to him. Only a few weeks ago, a Paper on the testing of large alternators was read at a Local Section meeting of the Institution, and now we have another. The first of these, by Mr. S. P. Smith, described a method of testing an alternator, which was an improvement of Behrend's short-circuit test, and enabled the machine to be run under full-load conditions, and to be tested for efficiency and temperature rise, without supplying any more than the total losses. This, though a very economical way of obtaining the necessary figures, had certain drawbacks, which prevented it from being readily accepted by practical engineers. The necessity of special connections of the field windings, and the uncertainty of the correctness of the iron losses, caused frequent difficulty. The Paper read by Dr. J. D. Coales before the Birmingham Local Section, and abstracted in this issue, also dealt with a means of testing large alternators without excessive power consumption, but more especially with a means of testing for pressure drop. To obtain a highly inductive load it has hitherto been necessary either to dismantle some of the test-room transformers, take off the yokes, and use the wound limbs as choking coils, or to obtain specially constructed choking coils similar to those described by Messrs. Morcom and Morris in their Paper before the Birmingham Local Section last session. Dr. Coales describes a method whereby the test-room transformers can be used for this purpose without dismantling them, by means of artificially saturating the iron, and under certain conditions this method will, no doubt, be of considerable use to the test engineer. Although primarily intended for a "pressure drop" test, the arrangement described by Dr. Coales could well be used for temperature and efficiency tests at varying power factors, as mentioned in the discussion, provided efficient means of cooling the overworked transformers were provided.

POWER SUPPLY IN LANCASHIRE

AN interesting fight is in progress between the Urban District Council of Radcliffe (Lancs.) and the Lancashire Electric Power Co. with regard to power supply within the township of Radcliffe itself. Although the Lancashire Power Co. has its large generating station at Radcliffe, it is precluded from supplying power within Radcliffe itself without the consent of the District Council. The Council has its own generating station, with a capacity of 490 kw. (made up by two 120-kw. sets and one 250-kw. set, from which it supplies 62 consumers for lighting, 16 for power, and 12 for light and power combined. To these consumers 285,186 units were supplied during the past year. The chief consumer of the Radcliffe District Council, however, is the Corporation of Bury, whose trams run into Radcliffe, and who have to buy electrical energy for this portion of their tramway system from the Radcliffe District Council at 1⅜d. per unit; 488,063 units were supplied to the tramways last year, and it is stated that the Bury Corporation are losing about £1,000 a year on this part of their tramway system.

The Radcliffe District Council, while not absolutely refusing to let the Lancashire Power Co. supply consumers in Radcliffe, makes it a condition that the consumers shall first make an actual application for power to the District Council, and then if the demand is so great that the municipal works could not deal with it, the consumer is allowed to buy from the Lancashire Power Co. This, it is said, has resulted in the power company having failed to get more than one consumer who would otherwise have been a good customer to them, for a consumer who desires to buy electrical energy from the power company naturally objects to applying for a supply from the District Council first, even if he is assured that this application is merely a futile formality.

The power company has, however, found an opportunity to make a determined effort not only to improve on these conditions, but also to add the Radcliffe District Council itself to the number of large consumers who are supplied from the company's mains in various parts of South Lancashire. The municipal electricity works at Radcliffe desire to put down more plant—to the extent of a 300-kw. set—to meet the growing demand for electricity in their district, and applied to the Local Government Board in the ordinary course for sanction to a loan of £14,350. Part of this, viz., £3,500, is for over-expenditure already incurred without sanction, £5,035 is for plant at the generating station, including the 300-kw. set, one boiler and some auxiliary plant, and the remaining £5,815 is for mains extensions and for motors for hiring out. At the Local Government Board inquiry, held on November 18th and December 10th, the Lancashire Electric Power Co. opposed the loan, and were supported by a section of the Radcliffe ratepayers, including several large manufacturing firms, on the ground that the District Council would fare more economically if they bought their supply "in bulk" from the company. Mr. Hooper, the Local Government Board inspector, allowed the company's *locus standi*, and the whole question of the District Council's attitude with regard to the power company's prospective consumers was gone into.

It appeared that the company had already offered to supply the District Council "in bulk" at the Council's electricity works at 0·6d. per unit for A.C. and 0·75d. for D.C. supply, but that this offer had been refused. The lowest price at which the Council were supplying any power-user was 0·9d. per unit; the power company, on the other hand, are supplying a large bleach works in the district with about 300,000 units per year at 0·65d. per unit. In answer to this, Mr. H. Wilkinson, the Council's electrical engineer, stated that his total costs last year were 0·78d. per unit sold, and that interest and sinking fund came out to 0·41d. per unit, while at the price mentioned for bulk supply taken from the company the costs would work out to 1·11d. per unit sold.

Mr. Wolfenden said that in 1905, at which time he was vice-chairman of the British Aluminium Company, the company had proposed to erect new works at Radcliffe, and had entered into negotiations with the Lancashire Power Co. They had practically come to terms for a supply of a 24-hour load (Sundays included) of 1,500 kw., but owing to the uncertainty and delay with regard to obtaining the Council's consent, the negotiations were broken off, and the British Aluminium Company erected in Norway the new works they had in contemplation. The Council contended, however, that there had been no unnecessary delay, as the matter had only come up in August, 1905, and that they were ready with the draft agreement between the Council and the company in the following November.

In the evidence given by Mr. Mills, the Clerk to the Council, it was elicited that the power company have to pay the Council 2½ per cent. on the gross revenue for the one consumer (already referred to) which they have in the Radcliffe area. This consumer is Whittaker's bleach works at Mount Zion. In the draft agreement with regard to the supply to the British Aluminium Co., only 1 per cent. was arranged. It was subsequently stated that the power company pay a similar 2½ per cent. to the District Councils at Ramsbottom and Farnworth, but only nominal considerations in Salford and Bury, and none in Bolton.

The Chairman of the Radcliffe Electricity Committee (Mr. S. R. Walker) was called to give his version of the negotiations with the British Aluminium Company, and stated that the plans for building the new works were passed by the Council in October, and the draft agreement in November, and that the breaking off of the negotiations was entirely due to the Aluminium Company. Mr. Walker admitted that the Council desired to confine themselves to supplying small consumers only, and on the question of taking supply in bulk, said that they could also obtain this from the electricity works of the Bury Corporation, which were only 2½ to 3 miles distant. Mr. Lacey, consulting electrical engineer to the Radcliffe Urban District Council, explained that the Council's present station at Radcliffe would not admit of the erection of a high-tension plant, and that the question of buying of bulk supply would in any case be considered before the existing buildings were extended.

In addition to the bleach works already mentioned, a number of other works were alluded to during the inquiry, of which some took power from the company and others did not do so because of the Council's intervention. Among the latter was the East Lancashire Paper Mill, which had put down its own plant. Messrs. W. T. Wood and Co., who were proposing to build a weaving shed in Radcliffe, went outside the area, as they found the Council's price prohibitive and could not make arrangements with the power company owing to the trouble with the Council. A similar position was taken up by Andrew Greenhaigh's bleaching works, which are owned by the Bleachers' Association, who also own Whittaker's bleaching works, the company's only power consumer in Radcliffe. Mr. Young, the manager of a new colliery at Coney Green, also said that his colliery would like to be in a position to get cheap electrical energy.

Mr. C. D. Taite, the present engineer and manager of the Lancashire Power Co., spoke as to the unworkable nature of the present arrangement with the Radcliffe Council with regard to applications for power, and of the necessity of being allowed to canvass in the district. In Salford, he said, they had a canvasser whose sole duty it was to call on power and light users.

Mr. Taite also adduced figures to show that it would pay the Council to buy energy in bulk from the power company at 0·75d. per unit for D.C. current. This offer was contingent upon an arrangement being come to with the Council for the company to deal directly with large power users. Mr. R. B. Leach, electrical engineer to the Farnworth Council, said that they had found that it was cheaper to take power in bulk from the Lancashire Electric Power Company before they had completed the building of their own generating station. He admitted that in the case of power users in Farnworth supplied direct by the company, a commission of 2½ per cent. was paid, but, on the other hand, it was stated that the Bolton Corporation charged no commission in such cases, and that the Bury Corporation only charged a nominal consideration. In Salford, too, permission had been given to supply a consumer in Prestwich on payment of a fee of £1 per annum.

Another argument adduced by the company was that the Radcliffe Council's electricity undertaking was only enabled to pay its way because of the contract with the Bury Corporation to supply its trams at 1⅜d. per unit, and that this price was too high, and would certainly be reduced, as it was subject to a revision every five years.

To meet a suggestion by the Radcliffe Council that assurances were needed as to the financial stability of the Lancashire Electric Power Company, Sir Richard Hampson, a director of the company and an ex-Lord Mayor of Liverpool, and also Mr. H. F. Parshall, chairman of the company, gave assurances that there were ample funds available both for working capital and for extensions.

The decision of the Local Government Board will be announced in due course.

ELECTRICITY SUPPLY AT ST. ALBANS

A Combined Refuse Destructor and Generating Plant

THE recently completed generating station at St. Albans, Herts, is in the almost unique position of being a steam generating station exclusively dependent on refuse for fuel. It forms one of the small separate stations owned by the North Metropolitan Electric Power Supply Co., which have been established in some of those isolated parts of its large area of supply (326 square miles), which it would not have been economical to reach by extensions of mains.

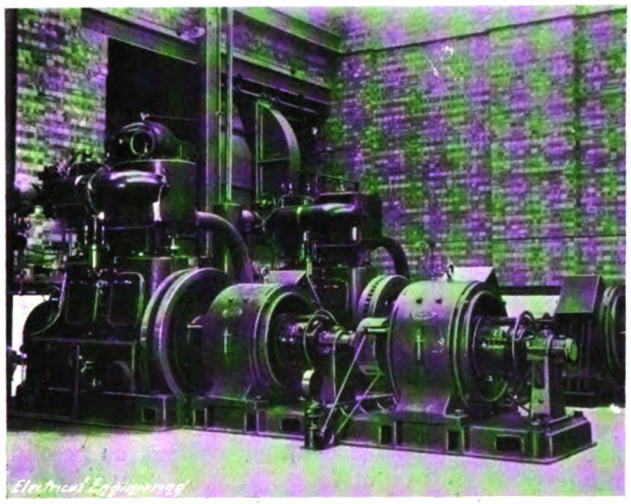

FIG. 1.—VIEW OF 150-KW. GENERATING SETS AND FORCED DRAUGHT PLANT.

The company also owns a station constructed for similar reasons at Hertford. By an arrangement with the Corporation of St. Albans, the company dispose of the whole of the town refuse which is dumped direct into a hopper delivering on to the floor of the destructor house, by the Corporation dust-carts. Before we describe the station itself, it may be of interest to give a few particulars of the history of the undertaking. As far back as in the year 1898, the St. Albans Corporation obtained a Provisional Order for the supply of electricity, but decided not to proceed with the construction of a station. Later, the Order was transferred to the St. Albans and District Electric Supply Company, Ltd., who, in 1905, obtained an Order for the supply of the surrounding district. An Amending Order in 1907 transferred both the above Orders to the North Metropolitan Electrical Power Distribution Company, Ltd., who now hold them, and the generating station has been built by, and is under the control of, the North Metropolitan Electric Power Supply Company.

The station is adjacent to a branch line of the Great Northern Railway within half a mile of the St. Albans station of the Midland Railway, and adjoins the works of Messrs. Arc Lamps, Ltd., which were described in ELECTRICAL ENGINEERING, Oct. 1st, 1908, page 489. At the time of that description, the works were run temporarily from a gas engine; but since then electric driving has been introduced, and power is supplied by means of overhead lines from the station now being described. As indicated in the ground plan of Fig. 5, an inclined roadway, laid with wooden sleepers in order to give the horses a firm footing, leads from the road to an elevated, covered in platform at the back of the station. Here the carts of refuse are first weighed on a Pooley weigh-bridge with ticket-printing attachment, and are then backed against the edge of a shoot which extends almost the whole width of the station as shown in Fig. 5. The refuse is dumped into this shoot and is delivered on to the destructor house floor below, from where it is fed by hand into the furnaces. Old iron is, of course, sorted out by the stokers, and any bulky objects, such as large mattresses or animal carcases, are cremated separately in one of the combustion chambers. The old iron is sold for about 15 shillings a ton. On either side of the main refuse hopper is a small coal-bunker, containing a small store of cheap coal of the class known as "yard sweepings." This is provided for the purpose of mixing with the refuse occasionally, when the material is very wet or contains a large proportion of garden refuse.

From the plan and elevation given in Fig. 5, it will be seen that the building is constructed in three main bays. The destructor furnaces, boilers, and pumping plant occupy the rear bay; the centre accommodates the generating sets and switchgear; and the front portion is devoted to the battery-room, test-room, and offices. A view of the generating plant, which comprises at present two 150-kw. sets, is given in Fig. 1. The arrangement of the boilers at right angles to the destructor furnaces, as shown in Figs. 4 and 5, has resulted in a very compact design for this portion of the plant. The end of the station from which the view of Fig. 1 was taken, is only temporary, and the site will permit of very considerable extensions. As can be seen from Figs. 1 and 5, the whole of the machinery and switchgear is quite shut off from the destructor plant, so that dust troubles are entirely obviated.

The destructor plant was supplied by Messrs. Heenan & Froude, Ltd., and consists of two units of three cells each. Each unit is capable of burning from 25 to 30 tons of refuse per day of 18 hours. The cells and combustion chambers are lined with 9 inches of fire-brick. Regulating valves for controlling the forced draught to each section of the grate independently are

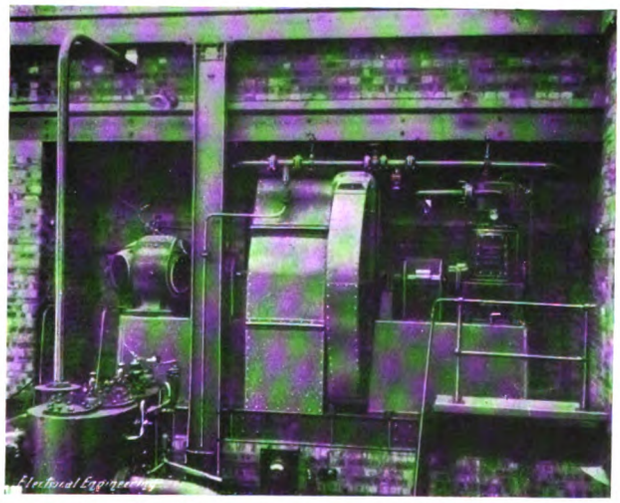

FIG. 2.—FAN FOR FORCED DRAUGHT WITH STEAM AND ELECTRIC DRIVE.

provided; and these are worked by means of small levers near the furnace doors. The latter are of the balanced sliding pattern. In order to permit of the destruction of mattresses, animal carcases, and other large articles, the doors of the combustion chambers, of which there are two, are 3 ft. wide by 4 ft. 6 in. high.

D

Digitized by Google

The chimney, which was constructed by the Alphons Custodis Co., is 130 ft. in height, and has an internal diameter at the top of 5 ft. 6 in. To provide forced draught for the furnaces a "Heenan" centrifugal fan running at a speed of 450 r.p.m., is used. As shown in Fig. 2, this fan can be driven either electrically or by steam. On one side is a vertical steam engine of the totally enclosed type, fitted with forced lubrication; this engine is connected to the fan by means of an ordinary flange coupling.

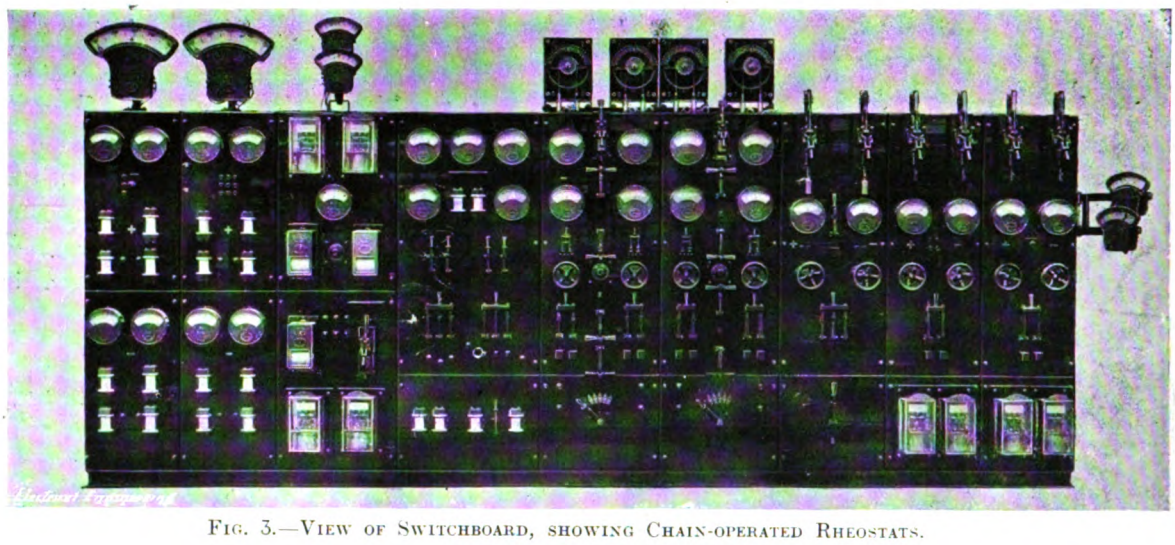

Fig. 3.—View of Switchboard, showing Chain-operated Rheostats.

On the other side is a 460-volt Rhodes ventilated type motor, which can be coupled to the fan by means of a sliding clutch when required. This motor is designed for a 50 per cent. speed variation by shunt regulation; the starting and regulating gear is attached to the wall just below the platform on which the forced draught plant is mounted. The platform is alongside the flue, projecting into the engine-room as shown in Fig. 1, but entirely separated by means of steel plates from the destructor house, so that no dust can reach either engine or motor. The air for the fan is taken in at the top of the destructor house, and after passing through the air-shaft and the fan, it is heated to a temperature of about 350° F. by being passed through an air-heater, which consists of a number of boiler tubes through which the flue gases pass, arranged in the flue in the position indicated in Fig. 4. The heated air is then passed through ducts to the front of the furnaces. Good ventilation of the destructor house is ensured, as fresh air is drawn in at the doorways and through special openings provided at the ground level, to replace that which is removed from the top of the building by the fan. This special feature of the Heenan destructor ensures that any smoke or fumes which may have collected in the destructor house pass through the furnaces a second time.

Each of the two Babcock and Wilcox boilers has a heating surface of nearly 2,000 square feet, and is composed of twelve sections of eight tubes each, and, as shown in Fig. 4, doors are provided in the side of the building, so that the tubes can readily be drawn when necessary. Each boiler is provided with a "Foster" superheater, capable of raising 7,000 lb. of steam per hour, at a pressure of 200 lb. per sq. in. to a temperature of 507° F., corresponding to a superheat of 120° F. These superheaters consist of a series of steel tubes fitted with annular gills or flanges not shown in the figure, to equalise the temperature. Each of these tubes has a centrally-supported core or closed tube, so that the steam, while receiving the superheat, passes along an annular space. The main and bye flues are provided with doors for access for cleaning. Two swivel dampers are fixed in the outlet to each boiler, and two balanced sliding dampers are provided in the bye flues; so that either destructor can be used when its boiler is shut down. There is also a sliding damper in the flue to the chimney. A guarantee was given by the makers of the destructor plant that 1·69 lb. of water from and at 212° F. would be evaporated per lb. of refuse burnt, at a pressure of 200 lbs. per sq. in., and at a temperature of 507° F. A pressure of 200 lb. per sq. in. was decided upon in order to take full advantage of the steam raised, so that blowing off would occur as seldom as possible. As a certain amount of blowing off is unavoidable, a relief valve is fitted at one end of the main steam range, and pipes are connected to it which allow

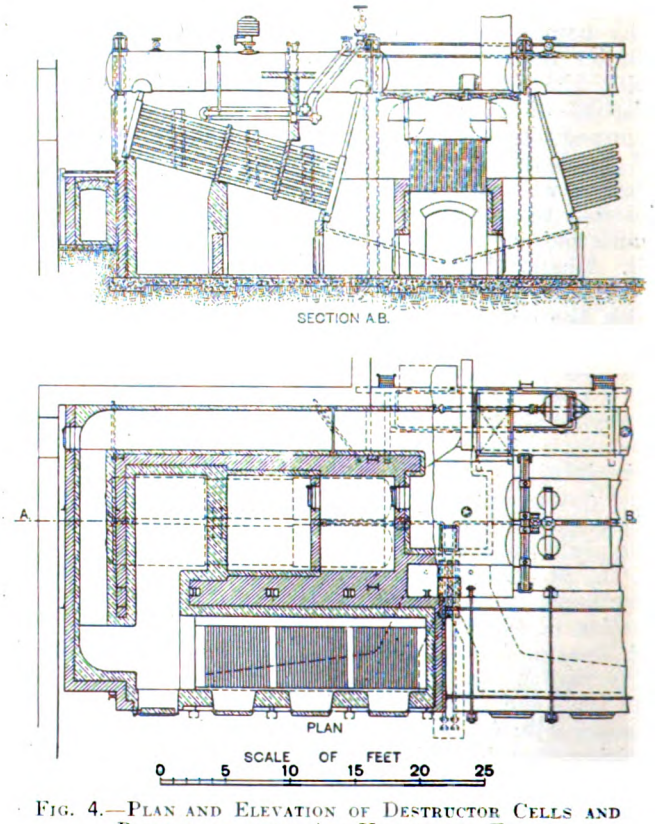

Fig. 4.—Plan and Elevation of Destructor Cells and Boilers, showing Air Heater and Fan.

the excess steam to pass to an injector heater in the feed tank, which not only increases the economy, but enables the water to be returned to the boilers. The amount of steam consumed by the engine for the forced

Digitized by Google

draught set was specified as from 5 to 6 per cent. of the total amount generated. Refuse clinker is, of course, a useful bye-product, as is also the fine hard dust collected from the combustion chambers, which makes an excellent mortar.

The two engines are of the Brush-Falcon two-crank compound enclosed type running at 430 r.p.m., and are at present run non-condensing, although it is intended to put in condensing plant at a future date. It is possible, however, that the exhaust steam will be utilised for the heating of a large factory and printing works adjacent to the station. The guaranteed steam consumption is 28·5 lbs. per kw. hr. at full load, with 175 lbs. per sq. in. pressure at the stop-valve and atmospheric exhaust. The pump room is situated above the main flue adjacent to the chimney, and contains a Mather & Platt three-throw variable stroke electrically-driven pump and a Wier steam pump. A water softening plant is shortly to be installed.

Each engine drives two 75-kw. continuous-current generators in tandem. These are four-pole Brush machines generating at 230 volts, one on either side of the 460-volt three-wire system. One of the problems which confronted the engineer when designing the station was the fact that, whereas a pressure of 460 volts had been decided upon for the town, the large factory and printing works already mentioned, which it was also intended to supply, had already a 115-volt system with its own generating plant. In order to obtain a 115-volt supply, the generator armatures are fitted with two slip-rings connected to opposite points in the winding, and these are connected through double-pole switches mounted on the machine frames with compensators. A tapping is taken out from the neutral point of each compensator, so that the direct-current voltage between either terminal and the tapping is 115 volts if the total pressure across the machine in question is 230 volts. Connections from the tappings of the two compensators and from the common and outer terminals of the generators thus constitute a five-wire system, from which the supply to the adjacent factory can be given. As the declared pressure in the town is 460 volts, and the station pressure may be as high as 480 volts at full load, provision is made to supply the difference between this and the total generator pressure of about

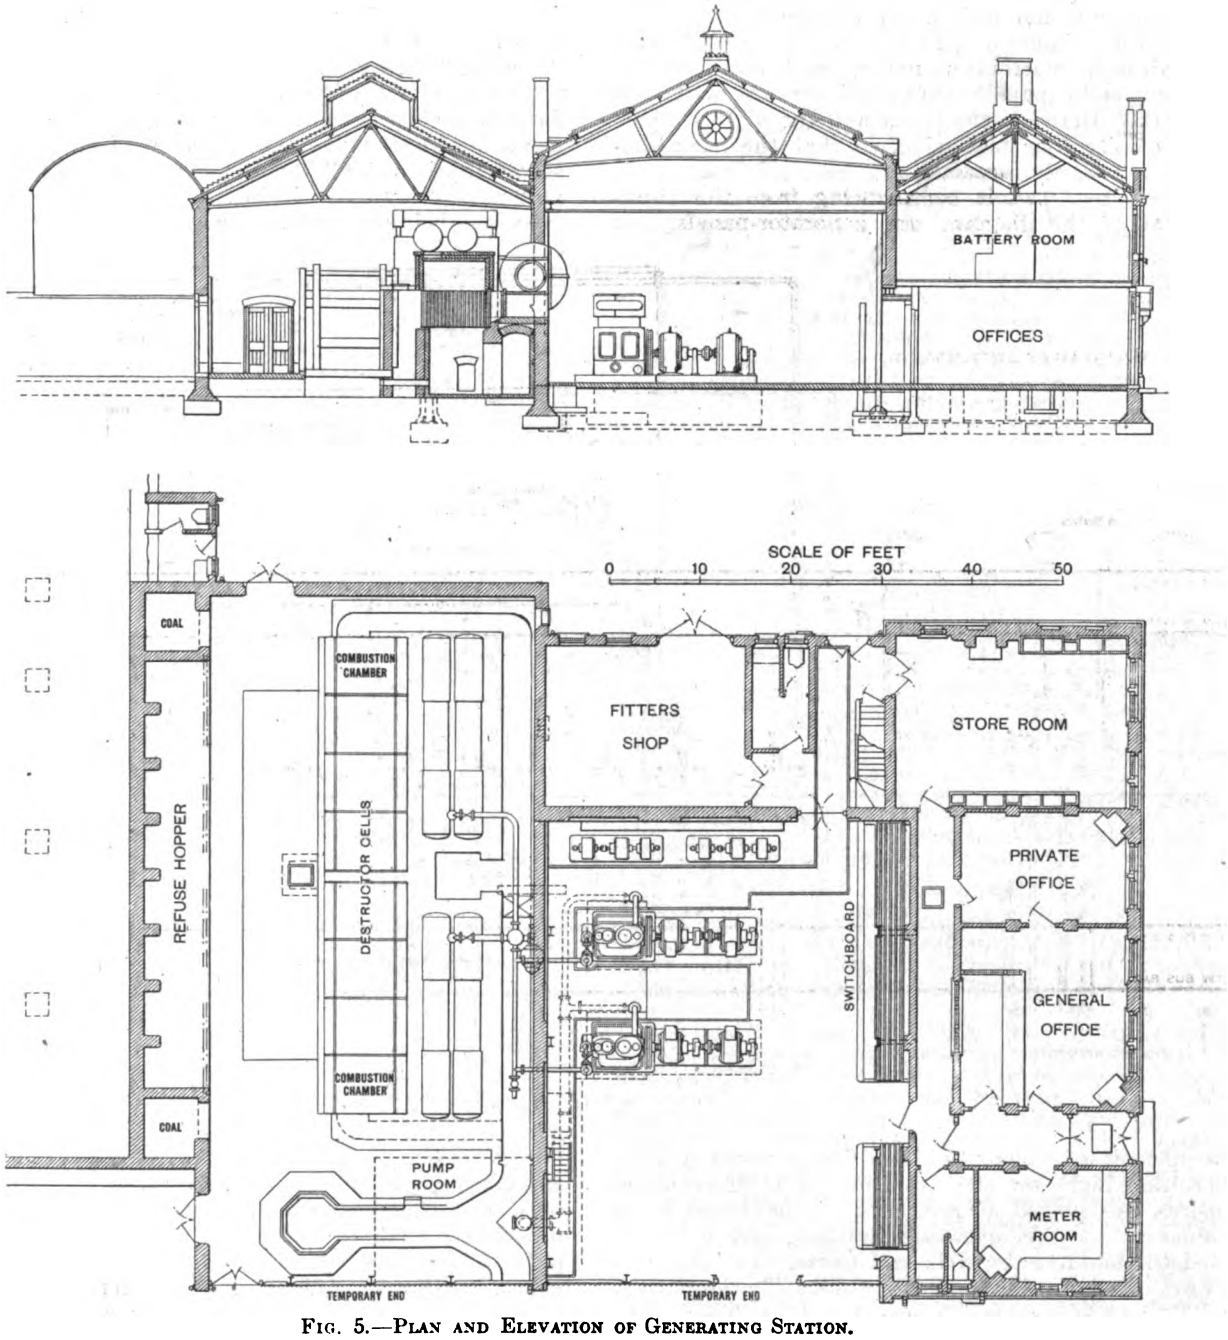

Fig. 5.—Plan and Elevation of Generating Station.

Digitized by Google

460 volts by boosters. For this purpose the generators are connected to "low-pressure" bars on the switchboard and the outgoing cables to the "high-pressure" bars, and the boosters are connected between the two sets of bars. The 115-volt supply can be given by using a booster set as a motor-generator set, in which case the generators can be connected direct to the "high-pressure" bars, as shown in the diagram of connections given in Fig. 6. This diagram, which shows the whole of the station connections, has been prepared to correspond exactly with the arrangement of the instruments and switchgear on the main switchboard which is illustrated in Fig. 3. The board itself is of Messrs. Ferranti's make, and consists of enamelled slate panels supported on an angle-iron framework. Between the board and the wall is a passage-way quite four feet wide, so that the back connections are easily accessible.

The first two panels commencing from the right-hand side of the diagram are generator-panels, and panel, the usual earth or neutral wire panel, the recording earth-current ammeter is fixed. A resistance is put in series with this recording instrument directly the earth-current reaches the value of 15 amperes, and this prevents it from exceeding that amount. The next two panels are the main feeder-panels, from which the 460-volt three-wire supply for the town leaves the station, the cables are six-core, and consist of two outers and a neutral, and three pilot cables from the feeding points on the town distributing network. These feeders, which together with the cables for the whole of the distributing mains were supplied by British Insulated and Helsby Cables, Ltd., are taken to "Prescot" feeder pillars.

The two reversible booster-sets supplied by the Lancashire Dynamo & Motor Co., are arranged along one side of the engine-room as shown in Fig. 5. Each set comprises a 460-volt, 800-r.p.m. shunt-wound motor driving two 18-kw. generators, the three machines being mounted on a common bedplate. The

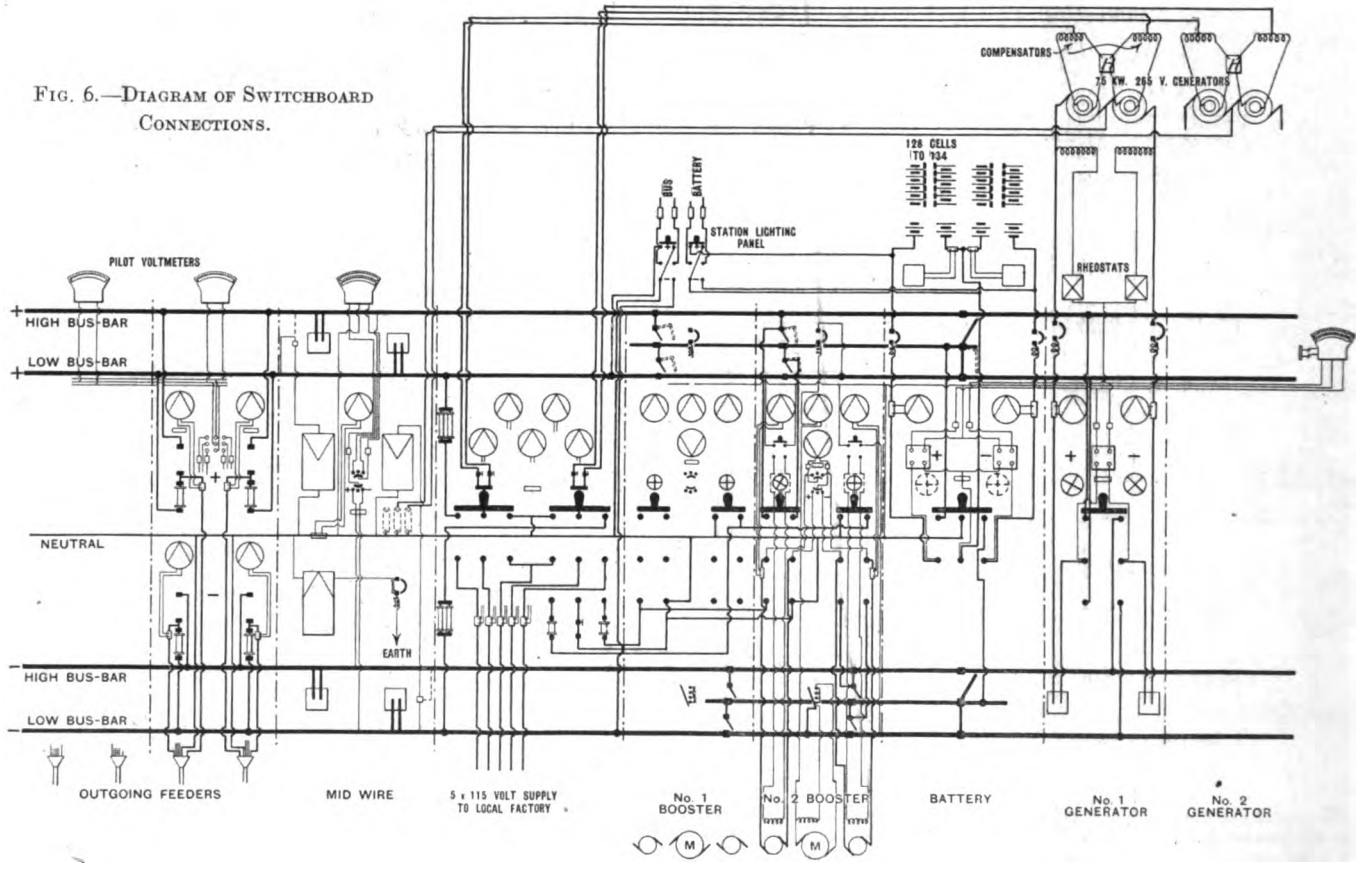

FIG. 6.—DIAGRAM OF SWITCHBOARD CONNECTIONS.

these permit of the generators being connected to either the high or the low bus-bars. The shunt rheostats are placed at the back of the board some distance above the operating handles, and are connected to the latter by rods and universal joints. On the next panel are the handles for operating the battery regulating switches, which are described later. The next panels, the booster-panels, are necessarily somewhat complicated, in view of the many functions of the booster-sets, but, by a careful inspection of the diagram, the manner in which the various connections are made may be seen. At the top of the diagram, and connections from the generator slip-rings to the compensators are shown, and the latter are connected to the five-wire supply cable in the manner indicated on the diagram of the next panel. It may be mentioned that the compensators are designed to take an out-of-balance load of 50 amperes in any one of the intermediate wires. The method of supplying the 115-volt system direct from booster-sets acting as motor-generators is also clearly shown. On the next two generator fields are excited from the 230-volt circuit through rheostats of the reversing potentiometer pattern. These rheostats, which can be seen in the illustration of the switchboard, are chain-operated, the rods connecting the chains being enclosed in insulating-tubes, so that if a chain breaks, there is no danger of a rod falling and short-circuiting any terminals at the back of the board. The booster-sets are used for three distinct purposes:—In the first place they are used for battery charging, and for this work each generator is capable of boosting up to the extent of 25 volts with a current of 200 amperes at the beginning of a charge, or 120 volts with a current of 150 amperes at the end of a charge. The second purpose for which these sets are used is for boosting-up between the high and low-pressure bus-bars of the station, as explained above, in which case one generator adds the necessary 10–15 volts on each side of the three-wire system. Thirdly, as mentioned before, the booster-sets can be used to give a 2 × 115-volt supply to the adjoining factory, when the main generators are not

Digitized by Google

running. By this arrangement, the supply to this special consumer from a portion of the battery only, and the consequent unequal discharge of the cells, are avoided. When performing this duty each set has a capacity of 150 amperes, at 2 × 120 volts, or 36 kw. The combined efficiency of one set when each booster is delivering 150 amperes at 120 volts is guaranteed to be over 80 per cent., and the consumption of the motor when the set is running light with the boosters unexcited is guaranteed to be less than 6 kw.

The battery room contains 268 cells arranged in one tier, but in two groups of 134 each. The cells, which are of the Tudor Company's make, have a capacity of somewhat over 1,000 ampere hours at a 10-hour discharge rate. Lead-lined wooden boxes are used, and these are supported on glass insulators, the whole being raised from the ground on a wooden stand. Some of the cells of each group are connected to the discharge regulating switches which, as indicated in the diagram of the switchboard connections given in Fig. 6, are operated by chaingear. Provision has been made for a bell connection, which will indicate when the switch arm is in an intermediate position. In order that the switchboard attendant may know in what position the switch arm of the regulating switch is, the shaft of the operating handle is provided with a screw-thread and a nut which travels along and indicates on an adjacent scale the number of cells in circuit. Ampere-hour meters to record the charge and discharge separately are provided. The station lighting is controlled from a small panel at the back of the main board as indicated in Fig. 6. All wiring is carried out with lead-covered twin wire.

In conclusion we wish to acknowledge our indebtedness to Mr. E. T. Ruthven-Murray, the Engineer-in-Chief to the North Metropolitan Electric Power Supply Co., who is responsible for the design of the station, for permission to visit and describe the station, and for kindly placing drawings and other information at our disposal. Our thanks are also due to Mr. T. E. Eachus, the resident engineer at St. Albans, who conducted our representative over the station.

SYSTEMS OF RECORDS FOR MAINS

Discussion at Sheffield

THE following is a report of the discussion on Mr. J. W. Beauchamp's Paper on "Plans and Records for Electrical Distribution Systems," read before the Leeds Local Section of the Institution of Electrical Engineers at Sheffield last week. An abstract of the Paper itself appeared in our last issue (p. 783).

Mr. J. E. Marsh (Sheffield Corporation Tramway), in opening the discussion, said that the subject was one which had been hitherto neglected by the members of the Institution, and congratulated the author on producing an eminently practical Paper. He was afraid that the keeping of complete detailed records of distribution systems did not always receive the careful attention by station engineers that was essential. He considered it very important to label cables to avoid mistakes on the spot. He was afraid, however, that the lead labels sometimes used were liable to be detached and then put back on the wrong cables.

Mr. J. W. Fawcett (Leeds) considered that the system described suffered from over elaboration. He maintained that a system of mains' records should be as simple as possible. The record was required for practical use and not compiled for academic consideration. Accuracy in detail was very important, and the speaker referred to a case where the records had failed—a particular cable having ultimately been found near the kerb, instead of being in the centre of the road, as shown. A system he found very satisfactory was to divide the network into from four to eight parts and make them into section maps. All services and extensions were kept in sketch books. He had tried both lead and leather labels with unsatisfactory results, and finally adopted aluminium labels punched in an automatic machine and attached by wires to the cables.

Mr. A. J. Cridge (Sheffield Corporation Electricity Supply Department) said that any system should be so arranged that a new man could easily understand it and find his way about without difficulty. He disagreed with a previous speaker, who had advocated recording the mains and service connections on the back of the meter card. The work should not be divided between two departments.

Mr. W. N. Y. King (Sheffield) emphasised the importance of keeping the records up to date, otherwise they were useless in an emergency and the system failed.

Mr. H. Dickinson (Chief Electrical Engineer, Leeds Corporation) explained in considerable detail the system adopted in Leeds, illustrating his remarks with copies of actual plans and cards in use. He had adopted a combination of ordnance maps and card systems. Every detail was shown on each section map and the cables were numbered, the numbers being carried forward to the end of the main. They worked absolutely to these maps. On the occurrence of a fault the particular map was referred to, a sketch made of the part required, and then worked to on the spot. They found no difficulty, as a rule, in getting all details on the maps. In some cases the maps were enlarged to twice the scale of the ordnance survey quite easily by means of a pantograph. All details referring to gas and water pipes, &c., met with were recorded, which information was frequently very useful. Photography was made use of extensively, and wherever an awkward place occurred it was photographed and properly indexed. He considered Mr. Beauchamp's system to be over elaborated, and was in favour of keeping a large part of the information in book form. All the plans were kept in a book and a duplicate set was preserved in the works, so that in case of fire there was no danger of the records being totally lost. In Leeds the card system only dealt with the consumers, feeders and sub-stations, from these they could easily turn to the proper book of plans, and in a few minutes every detail was before them. Photography was also used when laying mains for recording any peculiarity about walls, etc., which were then available as evidence at any future time.

Mr. W. F. Mylan (British Westinghouse Co., Sheffield) supported the previous speakers in advocating the importance of putting the working of a system into competent hands and keeping it strictly up to date. He preferred plenty of sketches and photographs to mere tabulated records; it was then so much easier to grasp a particular situation quickly.

Mr. Beauchamp, in reply, said the system advocated by him was intended to record where the cables were placed and not merely as a means of fault finding. It also gave a mass of detailed information useful for many other purposes besides cable laying. The automatic machine labels referred to by Mr. Fawcett were very useful for sub-station work and for switchboards. The use of photography advocated by Mr. Dickinson was valuable, especially if the records were carefully indexed. Referring to the remarks which had been made respecting keeping the records up to date, he agreed that the human element was a very serious one. Printing details on the cards served as a useful reminder of the information required. There was a liability in sketches to include only half of what should actually be recorded.

Somerset & District Electric Power Co.—Late notice is given of the intention of the Somerset & District Power Co. to introduce a Bill in the next session of Parliament for an amendment of their Act of 1903, including an extension of time for the commencement of works.

Northampton Institute.—In 1905 the Governors of the Northampton Institute applied to the Education Committee of the London County Council for a grant of £4,000 for the provision of electrical generating plant, but the Council recommended that a grant of £2,900 only should be made. The Governors of the Institute, however, were not able to put their plans into effect with this limited sum, and the amount was not spent. Application has now been made for a sum of £5,600, including the unexpended £2,900, for the provision of two 90 b.h.p. gas engines with suction gas producer plant, a 50-kw. continuous-current generator, a 50-k.v.a. three-phase alternator, a 25-kw. motor generator, and automatic reversible booster balancer set for a three-wire system; a 25-kw. rotary converter, four 10-k.v.a. static transformers, a battery of 250 cells, and two switchboards, one for continuous current and one for alternating current. The Education Committee recommend that this grant should be made, and the Finance Committee agree with this view.

Forthcoming Electrical Exhibition at Brescia.—Arrangements are being made for an international exhibition devoted to the application of electricity, to be held at Brescia next year. The province of Brescia is one particularly rich in water-power, and it is hoped that the exhibition will give an impetus to electrical power developments therefrom. The year 1909 has been chosen as the date for the exhibition as being the fiftieth anniversary of the inauguration of a monument to the famous Italian, Joseph Zanardelli. The exhibition will be also under the patronage of the municipality of Milan. The fourteen groups into which it is proposed to divide the exhibits cover a wide range of engineering and other applications of electricity and historical and statistical information relating thereto.

THE PRODUCTION OF NITRIC ACID BY ELECTRIC DISCHARGES

A LONG Paper entitled "The Electric Discharge and the Production of Nitrogen," by Messrs. W. Cramp and B. Hoyle, was discussed at the London meeting of the Institution of Electrical Engineers last Thursday, and also before the Manchester Local Section on the preceding Tuesday. In their introductory remarks the authors referred to the importance of the subject on account of the fact that it had been calculated that the amount of fertiliser in the form of natural nitrates still available was less than that required for the world's food supply for the next twenty years, assuming that no new sources are discovered. Many inventors have attempted to fix the nitrogen of the air by really attempting to burn the nitrogen

in the presence of oxygen to NO and NO_2 by means of the electric arc. The apparatus proposed by McDougall and Howles, of Manchester, and shown in Fig. 1, is essentially a high-voltage machine working at from 8,000 to 16,000 volts. The results given by this were very poor, but it is only fair to say that the power used was very small. Naville and Guye's arrangement is shown in Fig. 2. The arcs set up are in series, and the air to be burned is taken from the outside through the centre of hollow electrodes, thus passing right through the section of the arc. Three gaps in series are used. The apparatus of Kowalski and Moscicki (Fig. 3) is essentially arranged for high voltage and high frequency (from 6,000 to 10,000 ~ per second), and entails difficulties of insulation. These inventors

have also used direct current at 1,500 volts, giving 525 kg. per kilowatt-year. Bradley and Lovejoy combine a large number of small arcs (as in the last apparatus) with great length, obtained by drawing the arc out. The machine consists of a series of rotating electrodes which set up arcs and draw them out from fixed electrodes surrounding them, as shown in Fig. 4. The apparatus of Pauling is sufficiently clear from Fig. 5. It is really the reverse of the system used by Naville and Guye. The principle of Werner's apparatus is obvious from Fig. 6.

Birkeland and Eyde's arrangement is shown in Fig. 7. The machine consists of a pair of water-cooled copper tubes 15 mm. diameter employed as electrodes. These electrodes are suitable for flames up to 750 kw. at 3,500 volts, with a gap of 1 cm., and are placed in a magnetic field of about 4,000 to 5,000 lines of force per square centimetre in the centre. This field blows the arcs into the form of a large circular fan, the maximum diameter of the flame being about 140 cms. Fig. 8 shows the form of flame employed and the connections used. The object of the magnetic blow-out arrangement is to increase the rate of cutting of the flame and the air, which is also assisted by the air blast supplied. In the method adopted by E. Rossi, air at a high pressure (50 to 90 atmospheres) is heated by being brought into contact with a Nernst glower. Frank and Caro's process consists in forming first, in an electrical furnace, calcium car-

bide, and then passing nitrogen over this material when at a red heat, the result being that the nitrogen combines with the calcium carbide, forming cyanamide. It is essential for this process that the nitrogen should be free from oxygen, and this is obtained by fractional distillation of the air, so that oxygen is given off as a by-product.

In all the processes named above, except the last, the object is to produce NO_2+NO, which, when combined with water, gives a mixture of nitric and nitrous acids. From these is then usually produced nitrate of calcium, which is the fertiliser sold. In the last process the cyanamide is sold direct, and decomposes slowly in the presence of water, giving off ammonia, which is absorbed by the soil or taken up by the plants. Of the above methods, the last at present appears to yield the best result per horse-power expended, and from the point of view of cost is certainly better than Chili saltpetre already. Examination of records of outputs of the first seven processes shows us that the best results have always been obtained with very large

powers. Excellent results have been obtained by Bradley and Lovejoy from their multitude of small long direct-current arcs, and this result is to some extent verified by Moscicki's high yield obtained by the use of very high frequency discharges. The results of McDougall and Howles are poor. Little better is to be expected from either Naville and Guye or Pauling, and if there is one lesson more than another which can be learnt from these attempts, it is that an arc is never successful unless made use of to heat a very large quantity of air. The best results appear only to be obtained by the use of thin flames with very rapidly moving arc-threads used to heat suddenly quanti-

ties of air which are as quickly as possible cooled again. For this reason the apparatus selected for experimental results was a modification of that suggested by Werner.

The apparatus used in the authors' long series of experiments consisted of a high-tension transformer excited by means of an alternator and used to feed on its high-tension side a pair of phosphor-bronze ribbon electrodes shaped almost like the well-known horn lightning arresters. The nozzle *A* was supplied with air from an air-pump and receiver, so that the air had time to cool after being compressed before issuing from the nozzle. The alternator was a "Cramp self-excited" machine with a drooping characteristic and a frequency of 160. The

transformer had a ratio of transformation of 100 to 1. The details of the sparking electrodes will be seen from Fig. 10. After a short examination of various types, however, it was decided that a shape like that known as the "Laval" nozzle would be best as a general type.

The Paper then passed on to a general consideration of the various forms which electric discharges assume, and classified these as follows :—Glow, brush, spark, nitrogen flame (high-tension), and arc (low-tension). Experiments have shown that, by gradual increase of the current supplied to the low-tension side of a transformer, a spark between points on the high-tension side can certainly be caused to pass through every form successively in the order—glow, brush, oscillatory spark, nitrogen flame, and flaming arc. A curve for a discharge regulated in this way is shown in Fig. 11, where, with gradual increase of pressure across a pair of points, a glow is formed between

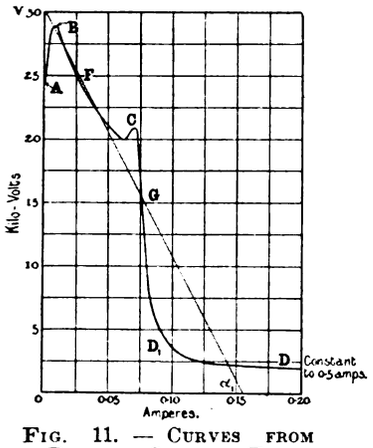

Fig. 11. — Curves from Primary Side of Transformer.

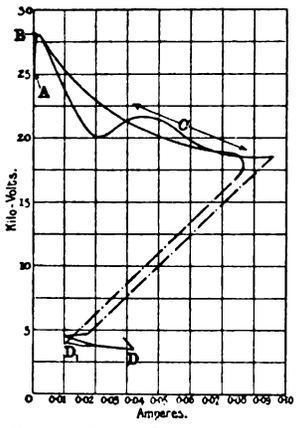

Fig. 12. — Curves from Secondary Side of Transformer.

the limits *A* and *B*. At *B* a brush discharge is set up, which gradually passes between *B* and *C* into the oscillatory discharge or spark. At *C* the latter breaks down into the high-tension arc or nitrogen flame, which continues to exist with great fall of pressure to the point *D*, after which the discharge is of the character of the ordinary low-tension arc. These characteristics and curves are correct so long as measurements are made on the low-tension side of the transformer, but if the readings of pressure and current be taken on the high-tension side, it is found that the transformer itself has considerable influence on the form of discharge. In order to test this, readings were taken using the 30-kw. 100,000-volt core-type transformer of the Municipal School of Technology. One series of results obtained is plotted in Fig. 12, where the letters used agree with those in Fig. 11. The great difference between Figs. 11 and 12 lies in the fact that the line *B C* is so much longer and so much more horizontal, and that *C D* has a negative slope in Fig. 12.

An elaborate study of this and other experiments has led the authors to the following conclusions :—(1) That each particular form of discharge is distinct from the others in having a different ratio $\frac{\delta V}{\delta A}$. (2) The glow discharge is the only one that, throughout its range, shows no negative ratio. (3) All the other forms have first a negative ratio, and then, usually, a positive ratio, as the current is steadily increased. (4) The form of discharge with the biggest negative ratio is the third form, the high-tension arc or nitrogen flame.

The authors, therefore, propose the following definitions :—The silent discharge, or glow, shall mean the first discharge taking place between the electrodes in air, whose characteristic $\frac{\delta V}{\delta A}$ is all positive. The brush discharge shall mean that discharge taking place with a hissing noise accompanied by light purple-coloured streamers projecting from the electrodes but not joining them. In this form of discharge the characteristic $\frac{\delta V}{\delta A}$ is nearly all negative. The spark discharge shall mean that discharge which succeeds the brush discharge, and whose characteristic $\frac{\delta V}{\delta A}$ is first negative (advanced brush discharge) and then usually positive. The high-tension discharge, or nitrogen flame, shall mean that discharge which, as the pressure is further increased, follows the sparking discharge, and whose characteristic $\frac{\delta V}{\delta A}$ is first negative, then positive. The low-tension arc shall mean that discharge which exists when the current is carried by the vapour of the electrodes and the spectrum is predominantly that of the material of the electrodes. Its characteristic is first negative and then positive.

The chemical characteristics of the five forms are fairly clearly marked. The glow and the brush discharges produce mainly ozone. The disruptive or spark discharge also produces a large proportion of ozone with a sensible proportion of oxides of nitrogen. The arcing flame is made up of arc-threads carried into this shape by the action of the heated air to which it gives rise, has a temperature far greater than the above, and is composed mainly of burning nitrogen, as is evident from the fact that a bottle inverted over the flame collects the well-known brown fumes of NO_2. There is no smell of ozone with this discharge. The well-known low-tension alternating-current arc differs from it in the fact that the conducting part is mainly composed of the vapours of the material of which the terminals are composed.

The effects on the steadiness, &c., of the various forms of discharge of variations in the resistance and reactances is briefly discussed.

The effects both of a current of air blowing on the discharge or of a magnetic field across it are the same effect so far as the form of discharge is concerned, for they tend to cause any small arc set up to travel rapidly at right angles to the field or along the line of the air stream. Consequently, the instant an arc is formed it travels away from the point of formation, under the influence of the air stream or the field, getting longer as it proceeds, and probably smaller in cross-section. This continues until it becomes of a length such as the terminal pressure will no longer support, when it is suddenly extinguished, and another starts from the points. Across the points themselves with this form of discharge there always exists the blue line of the oscillating spark, which continually renews the arc-thread. The effect of the travelling of the threads is to increase the mean length of the discharge so that the pressure across it likewise rises for a given current. To maintain such a discharge does not necessitate anything like the same amount of external resistance or reactance as is the case with a discharge of similar type without the air current.

The effect of an increase in the capacity of the circuit was found to be somewhat similar to an increase in the blast pressure and tended to increase the oscillatory current flowing across the air-gap, and to make the discharge yield ozone if it does not already do so, or increases the output of ozone if it was already being given off.

Results are given in the Paper of a long series of experiments with a view to determining the effects on the chemical results of the use of nozzles of different diameter, of change of current, of change of air velocity, of alteration of spark-gap length, and of change of capacity of the circuit.

The comparison of these variables was carried out as follows :—One variable having been decided upon, everything else in the circuit was kept constant. The air which passed through the discharge had a free exit, and a known portion of it was drawn off at a known rate by means of an aspirator through a flask con-

Digitized by Google

taining a weak solution of caustic soda of a known strength. This solution contained a little "Phenol-Thalene" as a colour indicator. As the gas was bubbled slowly through the flask the absorption of the oxides of nitrogen caused the indicator to lose its colour. The time taken for the colour to disappear completely was taken as a measure of the amount of acid produced in that time.

Regarding the size of the jet, it was found that the greater the amount of air passed by the jet for a given pressure, the greater is the maximum acid output, and the greater the amount of air passed by any given jet, the less is the maximum acid concentration. From this it follows that with increased quantity of air the amount of acid produced increases faster than the concentration diminishes, and therefore for a large yield per kilowatt-year with such an apparatus, a nozzle giving low concentration will probably be necessary.

Experiments with variations of current, air-gap length, and quantity of air passed indicated that increase of current gives an increased yield up to a certain maximum for each length of gap, and that the greater the quantity of air passed through the gap the higher is this maximum for each gap. In the course of these experiments the influence of the capacity of the electrostatic voltmeter on the secondary side was incidentally shown to be very marked.

The effect of frequency was much complicated by the presence of sharp peaks on some of the curves due to resonance effects. In this connection it was noticed that the higher the blast pressure, the more pronounced is resonance at certain currents, and that the higher the blast pressure, the higher is the value of the current at which oscillations are set up, and the more prominent they are.

The authors, while unable to give definite conclusions as to the effect of variations of frequency, think that it must also be allowed that the presence of a high frequency, in so far as it admits of large capacity currents across the arc and probable production of ozone, is to be considered on the whole as likely to increase the yield of peroxide. Consequently, they conclude that Kowalski and Moscicki are probably right in their statement, but that the reason for the increase in the output is not to be found in the actual increase of frequency, but rather in the increase of ozone due to this frequency as shown below. On the appearance of the discharge the effect of the voltmeter capacity, already alluded to in another connection, is very marked. It causes the blue oscillatory discharge, which always exists across the points, to be much enlarged in thickness and brilliancy, though the area of nitrogen flame is hardly increased. This would agree with the theory that part of the peroxide is due to the splitting up of ozone. Photographs of the discharge were shown which estimated the effect of adding the voltmeter very clearly. Since the ozone given off in the lower portion of the discharge is more active than ordinary oxygen, it is reasonable to suppose that more nitrogen will combine than before to form nitrous products.

Further confirmation of this view was obtained from a spectroscopic examination of the discharge, and a glass tube of small diameter was inserted into the high-frequency oscillatory portion of the discharge. Gas was then drawn off and tested, and was found to be rich in ozone. By suitably placing the tube in the discharge, air mixed with ozone could be obtained, whilst higher up in the same discharge air mixed with nitrogen oxides was obtained.

Some experiments were also tried with reference to the ionisation of the gases after formation. In the first place, it was found that the output could be sensibly improved by sudden cooling of the gases after leaving the apparatus, and a Tesla coil was connected to metal plates, between which the gases had to pass on their way to the testing apparatus, which showed that an increased output may be expected of from 5 to 20 per cent., depending upon the conditions existing. The authors' explanation was that when ionised molecules of oxygen and nitrogen pass through an electrostatic field, some of the uncombined elements may be forced together with such a velocity that chemical combination takes place between them. In this way an additional amount of peroxide is formed.

In the concluding portion of the Paper the authors endeavoured to show that the whole of the electrochemical phenomena discussed may be explained on recognised ionisation and electrochemical hypotheses. When first the potential difference is applied across the points, the electric field is very strong near them, and very weak near the centre. As a result, any ions produced near the points never reach the centre of the field; and since they are acted on by an alternating field, they are alternately driven out some distance and recalled. An increase in the pressure results in the motion at either pole getting more intense, so that with increased movement of the ions a glow appears at either pole. With further increased pressure the glow extends across from point to point as a double luminous cone, and at this time the velocity of the corpuscles is probably nearly enough to produce ionisation by collision. Further increase in the strength of the field results in not only the production of more ions from either side, but in the more rapid and complete interchange of the ions as they pass from one pole to the other. So soon as the stage is reached when free interchange can take place and when the kinetic energy of the ions exceeds the critical value necessary for ionisation by collision, there must be a corresponding reduction of the apparent resistance of the path. This leads to a formation of brush discharge with the first negative value of $\frac{\delta V}{\delta A}$. The heat of the terminals and consequent increase of corpuscles, with their production in turn of more ions by collision, leads to further reduction in the resistance of the path, so that the current is further increased. At this point further ionisation is assisted by the heat produced, until the terminals themselves probably supply the whole of the necessary corpuscles. When this happens the spectrum shows the character of the material of which the terminals are made, and we call it "the low-tension arc."

Now Töpler has, from facts similar to these for a continuous-current discharge, derived certain theoretical curves which agree very fairly with the experimental curves given in Figs. 11 and 12. Sir J. J. Thomson has shown that if the ionisation of air be taken as unity, then for oxygen it is 1·2 and for nitrogen it is 0·95. We may, therefore, assume that when electric stress first occurs across an air-gap, the oxygen is ionised before, or to a greater extent than, the nitrogen; and the smaller currents at this periods are probably carried by the oxygen ions alone. This leads to the formation of ozone, or to the burning or oxidation of oxygen itself. Thus when the air velocity through the air-gap is high, so that the glow or the brush only exist, the current is probably carried exclusively by oxygen ions, and hence the oxygen and ozone spectra only appear, and the gas smells strongly of ozone. As the field becomes stronger and ionisation by collision ensues, the nitrogen is ionised, and the brush gradually gives way first to the spark (which shows little nitrogen peroxide spectrum), and finally to the nitrogen flame. The temperature is undoubtedly far greater for this form than for the preceding, and the "body" is greater, for a draught of air hardly effects the ozone discharge, but blows the nitrogen flame about easily. This is explicable both on the ground of the oscillatory nature of the ozone discharge and also from the relatively small proportion of oxygen to nitrogen present.

The agreement of the quantity of gas actually formed with that which theoretically might be ionised under given conditions is very poor. Nor with the present state of knowledge could it be otherwise, for the data available as to the number of ions which may be formed in a cubic centimetre of air have been ascertained for limited temperatures probably of the order of 2,000° C. and with enormous pressures.

Further consideration of the above and other facts and theories, and the view of some thermo-chemists hold that the action whereby the peroxide is produced is neither a purely electric nor a chemical phenomenon, but only a thermal action, has led the authors to conclude that peroxide is formed in the arc by the combined agency of great temperature, great pressure, and great temperature gradient; that temperature and pressure may be interchanged, and that it is practically useless to attempt to set a limit to the maximum efficiency attainable till these relationships are better understood.

As regards practical deductions, attention was called to the great importance of adapting gap, current, and air blast to one another; for it is evident that changes of yield to the extent of 50 per cent. or more may be obtained by slight variations of either factor from the best obtainable. Again, it may be noticed that as regards quantity of air forced through the flame the maximum acid yield does not for a given current occur at the same point as the maximum acid strength; consequently there is reason to doubt the value of using a magnetic field (as does Birkeland) to spread out the flame. It would appear from rough estimations made on the Birkeland-Eyde process as if the efficiency of this system was such as to lead to the belief that a very good proportion of the maximum possible yield was being obtained. This is a most important point, for if this be true then it is hardly possible to compete with the cyanamide process in point of view of cost. If, on the other hand, by making use of the most favourable velocity, the most favourable gap-length, the introduction of ozone, the instantaneous cooling of whatever gas is produced, and fixing by subsequent ionisation, much better yields may be expected, then it is well worth while proceeding on these lines in a large plant with the object of rendering the production of NO more economical.

Appended to the Paper was a valuable bibliography of the subject.

DISCUSSION IN LONDON.

The SECRETARY read a communication from Dr. SILVANUS P. THOMPSON as follows :—

Messrs. Cramp and Hayle's Paper gives a very interesting *résumé* of the various suggestions that have been made for the production of nitrates from the air by electric discharges. Their own experiments are also extremely suggestive and valuable as throwing light on the molecular processes at work. I think the authors have hardly appreciated the importance of the spontaneous further oxidations of the gases which are formed in the passage of air through the flaming arcs used in the process of Birkeland and Eyde. The gases after leaving the furnace are not treated with water or lime until they have been allowed to remain (and cool) a considerable time in large oxidation chambers. If this were not done a very large proportion of the liquid formed in the water towers would be nitrous acid instead of nitric. It seems to me that the figure 900 kilogrammes of nitric acid per kilowatt year is too high a figure for the average commercial yield of this process. If I remember rightly, 900 was an exceptional figure, not an average one, the average being nearer 600. It is well that there should be no exaggeration, and I happen to know that in calculating the commercial project for the new and enlarged factories in Norway the experts expressly took a lower figure so as to have a margin of safety in their calculations. The large scale working of the new factory at Notodden has certainly shown a higher economical yield than that assumed in the estimates. The authors mention the cyanamide process, though this does not produce nitrates. There is no doubt that the two successful processes to-day are the nitrate of lime process and the cyanamide process, but though both of these take nitrogen from the air, the products are of different character, and nitrate of lime proves to be just as satisfactory for agricultural purposes as nitrate of soda, and in the case of heavy clay soils the lime in it gives a preference. Cyanamide on the other hand is akin to sulphate of ammonia rather than to nitrate of soda, and competes with the former rather than with the latter. Moreover, nitrate of lime has certain important applications in the coal-tar colour industry, for which cyanamide will not serve. A recent result of careful observations in Norway is that nitrites, hitherto regarded in agriculture as deleterious, are just as useful to vegetation as nitrates. This will enable a cheaper product of the electric oxidation furnace to be put into commerce. All electricians will do well to study the authors' discussion of the five types of electric discharge. Much vague and loose use is often made of the terms "brush" discharge and "glow" discharge; and often the production by sparks in the air of nitrous gases is confused with ozone. In fact, it is quite common to find any smell produced by electric discharges described as the smell of ozone.

Mr. BERTRAM BLOUNT, although called upon, declined to discuss the Paper seriously, as it was too physical in its nature for him. As regards the chemistry of the Paper, all he had to say was that it was of the most "guessy" description.

Mr. W. DUDDELL, F.R.S., referring to Fig. 12, said that he could not see how the discharge could very well have two stable conditions, corresponding to one definite current value. They had first 0·02 amperes for a stable condition of 3 kw. and another stable condition at about 20 kw., and he was led to suspect that there must be some other variable beyond the current, and that therefore really the figure should be drawn in three dimensions and not in two. With regard to the electrostatic voltmeter, he rather thought the thing was not so simple as it looked, and that they did not know what was meant by 0·02 amperes. He took it that the 0·02 was a root mean square value, but they did not know the maximum. In fact he thought they wanted to know a little more of the wave form of the current through these discharges before they could be quite clear as to what was meant by the curve. With regard to the effect of a current of air blowing upon the discharge, he wanted to know whether it was a fact that if the discharge was blown with a higher air pressure, they got less volts across the discharge. His impression of the arc in the past had been that if it were blown it always required a higher voltage to maintain it, and he was not at all clear as to what had occurred in these curves. In the same connection, the following sentence appeared in the Paper:— "Across the points themselves with this form of discharge, there always exists the blue line of the oscillating spark which continually renews the arc thread." It was not customary, he said, in wireless telegraphy to look upon the blue spark as being the oscillating spark, and he would like to know how the authors arrived at the conclusion that this was the oscillating part of the discharge. Further, when the authors stated that the discharge was oscillating, did they really mean oscillating in the ordinary sense. With regard to the effect of resonance in some of the experiments, he would like to know exactly what frequency that corresponded to. Was it the frequency of the alternating supply, or was it the frequency of the interruptions with which the sparking across the gaps took place? Sparks could take place, of course, across the gap between electrodes more than once per half-wave. Multiple sparking, for instance, was well known in wireless telegraphy where they got four, five, or six discharges across the electrodes in a half-wave. He would have been very interested to have seen the wave forms of some of these discharges, because he thought some of them must be extremely complicated, and that therefore the root square values of the quantities did not convey very much information as to what was going on. Some of the curves of output of acid shown had been plotted, so far as he could remember, in terms of the amperes in the primary. Now the amperes in the primary in a transformer of the type Mr. Cramp was using depended very little on the power that was being taken out of the secondary. It was purely a matter of the relation between the self induction of the secondary and the capacity of the secondary as to what amperes he was able to put through his primary. Therefore, it would have been of great interest if Mr. Cramp had given them the watts used, because in the commercial application of this system they would want to know how much power they were going to use. The effect of the putting in of an electrostatic voltmeter had really suggested this to him, for if this was an ordinary high tension transformer with a considerable self induction in the secondary winding, the putting in of the electrostatic voltmeter would considerably improve its power factor, and therefore the real reason that the output was greater might be that they were using more power.

Mr. G. N. HUNTLEY, in criticising the Paper from the chemical point of view, complained that nitric acid was not properly defined in the Paper. Nitric acid ordinarily had two meanings in commerce; there was 100 per cent. acid, but this was not the ordinary commercial article of 70 per cent. strength, and he rather thought the authors had worked upon the 70 per cent. basis, but the actual definition given in the Paper stated that commercial nitric acid was a mixture of nitrates and nitric acid. This was quite new to him, and it was not commercial nitric acid. If the figures in the Paper were worked out on the 100 per cent. basis, they would require considerable modification. He did not think the method used by the authors for estimating the nitric acid produced was a very satisfactory one. The measurement of the volume was very indirect, but leaving that on one side, the actual measurement of the acid was by simply measuring the volume of the gases produced, but from his experience with absorption plants, he was of the opinion that the quantities given by the authors were not reliable. In fact, the authors themselves had almost hinted as much in apologising for their method. Another source of error was that there was always moisture present in the air. There was one point he would like to see developed. All the workers on this subject seemed to have directed their attention to the output of nitric acid per kilowatt year, but the actual strength of the gas was also an important point. If this gas was passed through water they could get nitric acid at a perfectly definite strength, say 20 to 25 per cent., but the strength likely to be arrived at depended upon the concentration of the gases in the nitric oxide. He believed that in the apparatus of Birkeland there was ¾ per cent. nitric oxide, but in various modifications that had been introduced later this had gone up as high as 2 to 2½ per cent. This was of practical importance, because the cost of the energy might not be the chief consideration. The capital outlay upon the absorption plant had also to be considered, and the richer the gas the larger the plant had to be for a given quantity.

Dr. H. BORNS pointed out that the list of literature appended to the Paper appeared to him very defective. Whilst quoting Werner very largely in the Paper, there was no reference to his literature. Brode, some years ago, described the nature of the arc flame by means of a diagram similar to one given in the Paper. He referred to the greenish-blue flame over which there was an envelope of yellowish hue. The electric discharge of the chemical reaction took place chiefly in the blue flame. If a glass rod were put in this, the current and the potential at once altered, but when a glass rod was put in the other two zones there were no alterations; they were merely flame phenomena. This applied to a gas mixture, but if they burned the arc in a pure gas, then there was only one flame which was perfectly homogeneous, and his impression was that before the authors could say much about ionisation they should try to repeat their experiments as far as possible in pure gas. The arrangement of Moscicki's, described by the authors, was now no longer used. Concentric cylindrical anodes were used, in which the magnetic field was so arranged that the arc flame turned between the two, around the inner electrode, and up the annular air space. Moscicki worked with direct current. In fact, several investigators had proved that direct current and alternating current were equally efficient as regards yield when reduced to watts. This was an important point. Rosche, some years ago, used electrodes made of metallic oxides, and according to Clement, when an arc was formed between such electrodes, no resonance was formed at all. The use of metallic oxides for electrodes had been referred to in a remarkable Paper by Haber and Koenig, which was not mentioned by the authors at all. According to Nernst, the combustion of nitrogen was merely a thermal phenomenon, but according to others it was not. They knew that nitrogen and oxygen combined had a very high temperature, but that the resulting NO was decomposed at that temperature. Therefore, the object was to remove the NO as fast as possible out of the arc. It had also been

Digitized by Google

pointed out that as long as the decomposition and combination rates are equal then the electrical features predominate, and the reaction became essentially electrical. When, however, the decomposition was very rapid, relatively to the combination of the N.O., then the electrical features were of little influence. Experiments must then be considered on lines to permit of decomposition as fast as possible, keeping the arc as cold as possible. In any case, he thought they must start with pure gas first. In conclusion, Dr. Borns complained that the authors had mixed their system of measurement up in a most deplorable manner, cubic feet, inches, millimetres, and C.G.S. units all being made use of.

Mr. H. M. SAYERS said he had expected to find the Paper treat this subject a little more quantitatively as regards the possible efficiency of the process. The heat of formation of these oxides of nitrogen, he supposed, was known, and if the specific heat of the combining gases be also known for the best combining temperature, he took it that it could be worked out in watts or other energy equivalent per gramme, so that, given a certain amount of energy in the secondary circuit, they ought to be able to get the efficiency of the different processes just as it was possible to get the efficiency of a motor by measuring the input and the output. He did not find this in the Paper, however, and he would like to know whether the reason was that there was some uncertainty as to the actual heat of formation at the temperature of formation, or some other relation in the thermo-chemical application. Following the example of Mr. Duddell, he would like to ask a question as to the relation between the primary amperes in the different curves and tables, and the secondary amperes. He noticed that the current was measured in the electrostatic voltmeter, but he took it that the current through the discharge was not measured. If it was, perhaps the authors knew the actual ratio between the primary and the secondary currents in the different conditions on the curves. It occurred to him that this oxidation of nitrates was carried on by nature on a pretty large scale. Many of the higher plants did it, and they knew that there were some very remarkable microscopic plants which did it, and the properties of these plants could be used in a commercial way, and he believed they were used to a commercial extent. Was it not possible to measure the heat of formation of oxides of nitrogen by these microbes? If they had a number of these nitric acid or nitrate-forming microbes in a test tube with a proper thermo-electric arrangement, or one of Mr. Duddell's devices for these things, it should be possible to test the rise of temperature and find out the actual heat of formation and actual temperatures.

Mr. C. WEISS said that Dr. Borns had referred to the process for the working of which he understood that the Birkeland and Eyde Co. and the Badische Anilin und Soda Fabrik were now building large works conjointly. The patents, of course, of this latter company had been before the public for some years, and were extremely interesting, and he suggested that perhaps the authors could add this as a tenth example of previous work done in connection with the fixation of nitrogen. It was a matter which was coming before the public largely, and he understood that there were negotiations pending now for the adoption of it in this country.

Mr. W. CRAMP, in reply, said that when an electrical engineer took up a work in which chemistry, physics and electrical engineering were all mixed, he was likely to get into trouble, and it required a certain amount of courage to set about it. they had had many misgivings before writing the Paper, and the results would not have been published now except for the fact that they were unable to continue the work further. Many of the statements that had been made in the discussion were, he thought, a little hasty, inasmuch as he had only given a summary of the Paper, and some of the questions put to him were distinctly answered in the Paper itself. On the other hand, the authors had carefully left out certain important tests in their part to make the Paper short and concise. For instance, Dr. Thompson had referred to the spontaneous formation of N_2O_4, after the gases had left the flames. As a matter of fact, they had taken very great care over that. They had an apparatus covered with a large dome with the large contents compared with the amount of air blown through, thus giving ample chances of oxidation of NO, NO_2, N_2O_2, and N_2O_4, and they thought they had taken ample precautions to prevent NO escaping without being oxidised. They had also dealt with the difference in the cyanamide and nitrates and had compared them, as fertilisers, from the point of view of cost to the farmer, with the result that the cyanamide process was cheaper for the amount of fertilision produced for a given amount of energy. Mr. Blount had referred to the chemistry of the paper, and they admitted that it was rather guessy in this respect. They did not pretend to give absolute figures of output for the process, but comparative figures for the different conditions used. The idea was to enable someone now to produce a discharge as they had produced it, and, with the conditions which they thought they could lay down, start with the most economical process which they could suggest to work on in order to get a better result. They had given their explanation of the chemistry of the subject in the form in which it was given in order that there might be no mistake about what they were trying to consider. With regard to Mr. Huntley's remarks, if his figures were correct, he only brought their (the authors') figures out higher, but did not alter the proportional figures in any way, and, consequently, the comparative shapes of the curves, which were the things they laid stress upon, were still of importance, or, at least, they hoped of use. With regard to the measurement of absorption of these gases he thought he could fairly say that they had had in Manchester a good deal of experience in absorbing minute quantities of oxide of nitrogen. The chemist who helped them in this—namely, Mr. Peachy—had worked for a long time on the subject, and he advised this method of comparison because he had found that in testing the gases going through there was practically no peroxide escaping, and, again, it was not liable to error from the presence of ozone. Mr. Duddell's contribution to the discussion was, as usual, exceedingly interesting and valuable. He first referred to the stable conditions apparently shewn on the current curve, and he (Mr. Cramp) would like to remove any misunderstanding about Figures 11 and 12. In Figue 11 the measurements had been taken on the low tension side and were multiplied by the ratio of transformation in order to get an idea of the voltage appearing on the high tension side, and it must be clearly understood that no high tension voltmeter was on, except where it was definitely stated in the Paper. In Figure 12, the measurements were taken on the high tension side direct, and they were obliged to have a high tension voltmeter on. With regard to what they were resonating with, he thought the resonance was really with the multiple sparking, as Mr. Duddell suggested. They could not get an oscillograph that would give the shape of such rapid oscillations as they were using. A most important point was the question of power. They could not get a wattmeter that would give the readings of the power on the high tension side and their attempts to measure the power on the low tension side had not met with success. Consequently they could say very little about the change of power factor; undoubtedly it was changed, but to what extent he did not know. With regard to the measurement of volume and the relationship of volume and pressure they did not take these quite so roughly as some of the speakers seemed to think. They had a large air meter specially calibrated for the job, and every nozzle used was very carefully calibrated by means of that meter, together with a carefully calibrated pressure meter, so that they knew exactly the relationship between the volume and the pressure on each nozzle. With regard to Dr. Borns' remarks, they were glad to have his additions to the list of literature on the subject, which they knew was not complete. He had not given Werner credit for any writings, because he did not believe Werner had ever written anything at all. They quite agreed with Dr. Borns that all these experiments ought to be started with pure gases, but that was chemical-physical work, and could not be undertaken in a commercial warehouse where they had had to carry out their experiments. Dr. Borns had also mentioned Moscicki's new continuous current process, which, as a matter of fact, the authors had referred to in the Paper. Mr. Sayers had made some very interesting remarks about the theoretical heats of formation, but he did not think it was possible to get the efficiency of the flame as Mr. Sayers had suggested until they knew something more about the heats of formation. They could not measure the temperature of the flame and they did not know the exact energy dissipated in it, and he knew of no figures published on this subject.

DISCUSSION IN MANCHESTER.

The discussion was opened by Dr. E. W. MARCHANT (Liverpool University), who asked for some further information as to the effect of the character of the circuit on the curves given in the Paper, and gathered from some of the results that the transformer employed was one with rather bad regulating qualities. Another small detail that he wished to refer to was the initial spark mentioned as occurring before all discharges took place. He had noticed the same thing in connection with an oscillating discharge with a frequency of about 10,000 per second. The pilot spark occurred before there was any sign of oscillation, and he took it to be due to the discharge terminals, and thought that had been rather borne out to-night by the author, who had shown that the initial spark was largely increased if they had a voltmeter of some capacity connected across their terminals. He was interested in the theory of ozone helping to produce nitric acid, and mentioned the corrosion which occurred of these fittings of large influence machines, which might be due to nitric acid formed by the agency of the ozone produced by brush discharges.

Mr. C. F. SMITH considered that a good deal of importance attached to the effect of the nature of the circuit, especially at high frequencies, and referred to the great irregularities in the distribution of the voltage drop in different parts of the circuit in the case of high oscillation frequencies. Referring to a photograph of the discharge from a "horn" arrester which Mr. Cramp had shown, he was inclined to think that a larger proportion of the effect was due rather to the magnetic field of the current than

Digitized by Google

the air current, and this would be shown by putting the horns upside down.

Prof. W. H. Haldane Gee (Manchester Municipal School of Technology) emphasised the necessity for a very cheap supply of current for such processes to be commercially practicable. There were certain great principles that might be applied in studying the combination of nitrogen and oxygen. First of all, we knew that it was endothermic, and that the resulting compound would be decomposed by heat. Nernst, by passing air through an iridium tube, had been able to measure the percentage of N_2O_2 at various temperatures up to about 2,000° C., and his formulæ might be extended to higher temperatures. Birkeland and Eyde had shown that, taking the best available data, the output of their furnace was somewhere about what would be expected from Nernst's formula. This was a very important matter, because, unless the yield could be increased very largely, the nitrogen-oxygen process did not seem to compare favourably with the cyanamide process. Now, Mr. Cramp had shown that, by the use of the Tesla coil, the introduction of ozone, and so on, that we not only got a thermal action, but also ionic changes that would give a greater yield of the nitrogen dioxide. Two Russian Professors (Gorbey and Mitkievitch) had been experimenting on the combination of nitrogen and oxygen. They used a simple type of furnace. Air was passed over two electric flames, using electrodes of carbon or metal, and then they cool the resulting gas. It was said that the yield of a 12-kw. plant was as good as the large plant used in Norway. He asked for further particulars as to how the sparks pressure was calculated.

Mr. J. Lustgarten, referring to Mr. Cramp's ionisation theory, wished to ask how the ions in the first place were produced. The way he took the ionisation theory to explain the manner in which the glow first starts, and, consequently, the brush discharge, and the other various forms of discharge, was somewhat as follows: Free ions were always present in atmospheric air. As soon as the pressure was applied between the two points, the ions started to move, and their velocity increased with the strength of field. With the increase of velocity, collision took place between these free ions and the molecules of the gas, with the result that further negative and positive ions were produced. Now this went on until the kinetic energy of the ions due to the increase in field that was applied between the two points became large enough, and the glow appeared.

Mr. E. A. Watson wished to add yet another explanation of the glow brush and spark discharge. Consider two sharp points placed in an insulating medium with a difference of potential between them. From the principles of electrostatics, the dielectric stress in the medium at the points would, if the points were perfectly sharp, and if the medium were not disrupted, be infinitely great. This was, of course, impossible, and what actually happened was that the point surrounded itself with a zone of disrupted medium, in this case air, roughly spherical in shape. The dielectric stress at the surface of such a sphere can easily be shown to be finite, and less than the previous stress at the point, so that the effect of the disruption was to relieve the dielectric stress on the air, and to enable a stable condition of affairs to be maintained, irrespective of the characteristics of the circuit employed. When the voltage was increased, the zone of disrupted air would grow in size until it reached a certain critical value, at which any further increase in its diameter would increase the dielectric stress in the remainder of the air. The condition then became unstable, and the brush discharge took place. This, unlike the glow discharge, was affected by the resistance, reactance, &c., in circuit. If the transformer and alternator used were of large capacity, it could not be obtained, but the discharge passed straight from the glow to the spark.

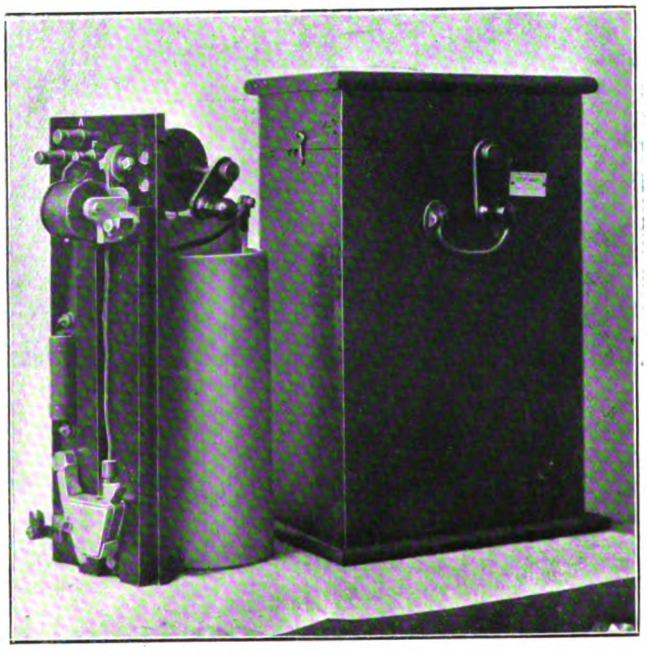
Mr. P. Kemp said that it was interesting to compare Figs. 11 and 12 with ordinary curves of current and voltage. At first the current and volts increased in agreement with Ohm's law, and then the current remained practically constant for a large increase in voltage. This corresponded to the part marked *A B* in the curve, where the current was very nearly constant, whilst the voltage increased largely. At the point corresponding to *B*, the curve for parallel plates bent sharply upwards, this being the stage when fresh ions were produced, and a large increase of current was produced by a comparatively small increase of pressure. If, now, the air-gap were decreased, even a reduced pressure would be sufficient to cause a substantial increase of current. This corresponded to the section *B C* during during which the brush discharge took place, and the layers of air nearest the electrode became broken down. In this way the effective length of the air-gap was reduced, and the cases were seen to be analogous; but at this point a peculiar rise in pressure is observed which was difficult of satisfactory explanation. The section *C D* was evidently due to the C R drop produced in the H.T. spark and nitrogen flame, to say nothing of the drop in the transformer. Since the pressure was high at the instant the pilot spark passed, a considerable load was put on the transformer, thus producing the sudden drop in pressure. The low-tension arc was now established, and the ions were torn off from the surface of the electrodes, practically forming a flexible conductor of the arc. It is not essential that a discharge should go through all the five stages enumerated by Mr. Cramp. The spark may take place before the brush discharge appears.

Mr. W. A. Stephens objected to the authors' conclusion that in a glow or brush discharge with high air velocity, the current was carried exclusively by the oxygen ions on account of the relative velocities of the nitrogen and oxygen ions.

Mr. Cramp, in reply to Dr. Marchant, explained the difficulties in obtaining the exact circuit conditions. With regard to the necessity for cheap power mentioned by Prof. Gee, in Norway they were able to produce it at a very low price, and at the present time, to his certain knowledge, in Ireland there was a waterfall of at least 30,000 h.p. with men there ready to put in a plant to harness that power, but it was almost impossible in this country to raise capital for the use of it. Mr. Lustgarten's remarks with regard to glow ionisation were interesting, but they did not agree with his ideas. It had been clearly shown by Sir J. J. Thomson that ionisation took place due to an electrostatic field, and that was all that was wanted to start the action. With regard to Mr. Kemp's remarks as to the first spark that passed, he thought the effect was of the nature of a surge, and could not be maintained; consequently, with the gradual increase in pressure, the five stages were always passed through.

A NEW LIQUID STARTER

THE accompanying illustration represents a new pattern of liquid motor starter, which is being put on the market by the O.S. Liquid Starter and Dimmer Co., of Leigh, Lancashire, under the Olive and Swarbrick patents, and is standardised up to 50 h.p. The firm have given a good deal of attention to the choice of a suitable electrolyte, and are able to supply material for a solution which gives no trouble through creeping, spraying, or evaporation. An efficient no-voltage release is provided, and the starter falls to the off position by gravity, as soon as there is any appreciable diminution of voltage across the armature.



O.S. Liquid Motor Starter.

When the starter is full on the electrodes are short circuited, and a good point in the arrangement is that the resistance is never in series with the field circuit. Special care is taken in the selection of the jars, which are of the best non-absorbent Doulton ware, without joints. The whole of the mechanism can be taken to pieces for inspection or repair in an instant. Two connections only need disconnecting, and the whole of the working parts can be simply lifted out.

Telegraphic Traffic.—The Hanekin route, and the cable between Dakar and Consky, Africa, have been restored to working order again, and there are no interruptions to record.

Electrolytic Disinfectant.—The *Standard* states that a company is being floated in Durban, which will in all probability erect a factory there, for working an electrolytic process for the production of disinfectant from sea-water. The company in question is said to have acquired all the rights for South Africa and Rhodesia.

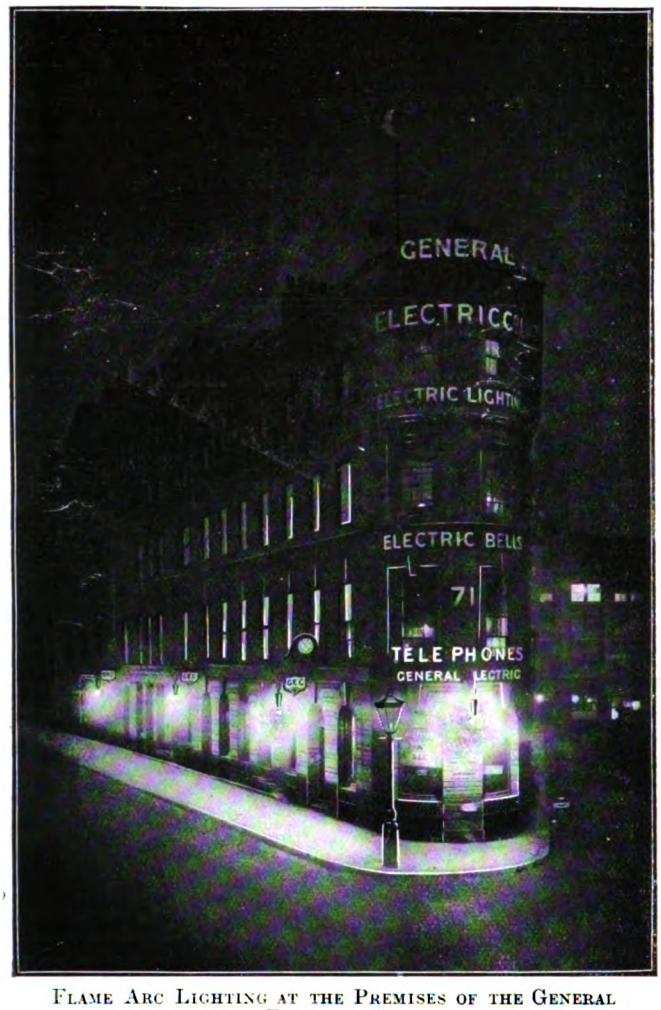
STREET ILLUMINATION BY FLAME ARC LAMPS

THE question of long burning flame arc lamps for street lighting is attracting a good deal of attention at the present time, and interest will attach in this connection to the display of lamps of this nature, which is now being made outside the premises of the General Electric Co., in Queen Victoria Street. The effect produced is shown in the accompanying illustration.



Flame Arc Lighting at the Premises of the General Electric Co.

which is reproduced from a photograph taken recently between five and six o'clock on a slightly foggy afternoon. The four lamps in question are examples of the latest pattern of Angold magazine flame arc lamp, which the company have developed specially for street lighting purposes. These lamps, although of very moderate size, are constructed to run for 55 hours without trimming.

London Electric Power Bills.—The House of Lords has accepted the Commons' amendments to the London Electric Supply Bill and the London (Westminster and Kensington) Electric Supply Bill, which we gave at length in our last issue. The Bills received Royal assent on Monday.

The Mile End-road Tramway.—In answer to a question by Sir John Benn in the House of Commons last week, Mr. Winston Churchill stated that accidents to two persons and five horses had been reported to the Board of Trade as occurring upon the G.B. surface contact line in the Mile End-road through contact with live studs. The service in question was withdrawn in July last and the period covered by the Board of Trade certificate expired last Wednesday.

The Brighton Railway Electrification.—A good deal of progress has been made with the equipment upon the single-phase system of the Victoria-London Bridge suburban section of the London, Brighton and South Coast Railway. It is stated that the overhead equipment is already complete from Battersea to Denmark Hill, and its completion as far as Peckham Rye will enable experimental running on this section to be commenced early in January. On the rest of the line, except in the termini, practically all the overhead steel work is up, but the catenary construction is not yet installed. The feeder cables are, however, all laid, and the switch cabins are complete. Eight complete three-car trains are also ready for trial.

ELECTRICAL HEATING AND COOKING APPARATUS

A PAPER was read recently by Mr. S. R. Gibbon, before the Liverpool and District Electrical Association, on electricity as applied to heating and cooking. After a few historical notes, the author classified heating systems as electrolytic and hot wire, further subdividing the latter into incandescent lamps, hot wire coils, hot wire coils in enamel, hot films, and hot iron plates (transformer method).

The only commercial example of the electrolytic method was the Fuller Geyser, which gives a continuous stream of two pints per minute of hot water with 1·5 kw., and the use of the incandescent lamp as a heater was limited to radiator and medical appliances. In the hot-wire system as developed by the Phœnix Electric Co., there is no form of insulation round the wire, as they contend that this hinders the radiation and conduction of the heat generated. Further, there is every care taken to allow of perfect expansion and contraction of the wire, which is of special alloy. It is enclosed in a specially constructed case giving rapid and highly efficient conduction.

The enamel method in use is the General Electric Co.'s "Archer" system for the smaller appliances. A bottom layer of semi-refractory material is first fused on to the metal base. On this coating are laid wires of a special composition, crimped in such a way as to render them non-inductive, and embedded in a further layer of enamel, and covered by another layer. In this way the whole forms one solid mass. In this system the conductor can be brought within 0·036 in. of the object to be heated, and an efficiency as high as 90 to 97 per cent. is obtained.

The enamel system is not, however, employed in the ovens manufactured by the General Electric Co., but spiral coils of special wire are wound cylindrically round porcelain insulators. The elements are of comparatively small dimensions, and are easily replaceable. A valuable feature to some of the General Electric Co.'s water-heater, &c., is a fusible plug which protects the appliance from overheating by cutting the current off, should the vessel be left dry with the current on.

The Prometheus system consists, primarily, of resistances composed of metallic films deposited on insulating bases. For the latter, thin mica strips are employed, and the film is protected from mechanical injury by enclosure in a metal case, from which it is efficiently insulated. Electrical continuity is established by means of flat metal terminals held in close contact with the two ends of the film. A number of different forms of these resistances or "elements" are used, each suited to the particular conditions under which it has to work, and the size and shape of the apparatus on which it is employed.

Finally, as an example of the transformer method, the author mentioned the "Tricity" cooker of the Berry Construction Co., in which the part of the apparatus representing the stove is formed by a transformer, the top of which forms a hot plate, and which induces currents in windings embedded in the actual cooking vessels laid on the plate, so that flexible wires are entirely avoided.

The author, in conclusion, described the "Electroyl Radiator" of Messrs. Purcell & Nobbs, in which a high efficiency from the air-warming point of view is obtained by the heating to a moderate temperature of a considerable body of oil contained in a vessel with large surface by immersed wires. This apparatus was described and illustrated in Electrical Engineering, October 29th, page 586.

Electric Head Lamps.—It is announced in the *Electrical Review and Western Electrician*, that the street sweepers who have to work at night in the "boulevards and parkways" of Chicago, are to be provided with small electric lamps to their caps, in order to prevent risk of their being run down by rapid traffic. Two-volt tungsten lamps are used, supplied from a pocket one-cell accumulator.

Electrification of the Pennsylvania Railroad.—It is announced in the *Electric Railway Journal* (New York), that a decision has been arrived at to adopt the continuous-current, third-rail system for the North and East River tunnels and lines in connection therewith. The conclusion has only been reached after extensive experimental observations with both this and single-phase methods. Extensive comparative tests of locomotives have been in progress for the last two years on the West Jersey and Seashore Railway, and a special test line was erected in Long Island with short lengths of no less than ten different patterns of overhead construction, including dummy tunnels, for the study of single-phase working. The experimental rolling stock included a special 11,000-volt 15-cycle locomotive, and other vehicles, from which complete trains were made up.

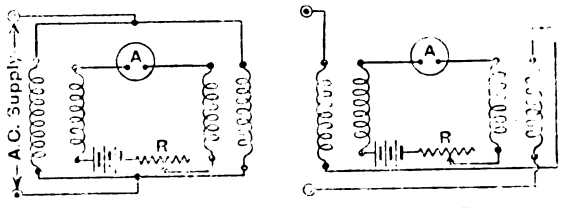
THE USE OF TRANSFORMERS AS CHOKING COILS FOR THE TESTING OF ALTERNATORS

In his Paper, read on Wednesday, December 16th, before the Birmingham Local Section of the Institution of Electrical Engineers, Dr. J. D. Coales, of Birmingham University, described a method whereby ordinary transformers could be used as choking coils for the purpose of testing alternators on inductive loads. In attempting to separate the inductive and resistance components of the "drop" in alternators on load, it is necessary to apply an inductive load about equal to the full-load current of the alternator under test. The smallness of the no-load current renders a transformer useless as an inductive load at the voltage for which it is designed unless by some special means the no-load current can be increased to a reasonably large value. In core transformers with butt joints this may be accomplished by temporarily opening the joints between the limbs and yoke, and inserting distance-pieces of non-magnetic material, but this is not always convenient. To provide choking coils for such a purpose is generally too costly, especially in the case of large alternators. If, however, the alternator is provided with transformers either for stepping its voltage up or down or both, the test may be easily carried out by the method described in the Paper, which permits of a reduction of the permeability of the core of a transformer (thereby increasing its magnetising current), without any interference with its construction. Briefly, the method consists in bringing the flux density of the core to a high value, by means of direct current sent through the secondary winding; so that when an alternating electromotive force is applied to the primary, the flux density undergoes variations about a mean flux density corresponding to low permeability, instead of about zero flux density corresponding to high permeability as is ordinarily the case.

In the use of this method it is evident that something must be done to prevent the secondary electromotive force from driving an alternating current through the source of direct current. Two ways of doing this are shown in Figs. 1 and 2. In Fig. 1 the primaries of two similar transformers are connected in parallel, and the secondaries in opposition as in the Kapp-Sumpner circulation of power test, the source of direct current being inserted as shown. In Fig. 2 the primaries are in series, and the secondaries in opposition as before. The inductance of the second arrangement is double that of the first, and by use of both a wide range of inductances may be obtained. In the absence of a specially designed choking coil, it is thus necessary to use two transformers for single-phase working. For testing a three-phase alternator, at least three transformers are necessary. If two sets—that is, six transformers—are available, then an inductive load may be obtained by making up three single-phase pairs connected as in Figs. 1 and 2, and combining these in star or mesh groupings with the direct current sent through the six secondary windings in series; or each three-phase set may be star connected, and the two sets connected in parallel with the secondaries opposing each other as in the Kapp-Sumpner test applied to three-phase transformers. The source of direct current is then connected between the neutral junctions of the two sets of secondary windings.

If the high-tension windings are used for the direct-current



Figs. 1 and 2.—Alternative Arrangements of Transformers.

circuit, the strength of the direct-current required is proportionately reduced. There are several methods of arranging the direct-current circuit in star- and mesh-connected transformers, and it is possible to superpose the direct current upon the alternating current in the primary windings in such a way as to avoid any circulation of direct current through the alternator circuits. This is equally true both for full inductive and partially inductive loads.

In the tests described by the author, only three transformers were available, and mesh connection was adopted for both the primary and secondary windings of the transformers. The direct current was caused to circulate round the secondary mesh consisting of the high-tension windings, by opening the mesh at one corner and inserting a battery, carbon rheostat, and ammeter. As there is no alternating electromotive force round such a mesh under ordinary circumstances, the direct-current circuit would experience no alternating current of any magnitude. However, should such circulating currents occur through dissymmetry produced by the artificial saturation of the cores, it may be reduced to a negligible amount by means of an ordinary choking coil inserted in the direct-current leads. The connections for taking a full inductive load test on an alternator in this manner are given in Fig. 3. The results of tests made by the author, according to the above method, and also with three ordinary choking coils connected in mesh, were given in the Paper, and a comparison of these results shows that with full-load current the transformers caused a drop of 46 per cent. and the choking coils a drop of 47·5 per cent.—that is, a difference of 1·5 per cent. In other words, the error by using the transformers was 3·1 per cent. If six transformers had been available, so that in each phase the windings could have been connected as in Figs. 1 or 2, the author concludes that the results would have been exactly the same by the two methods. By connecting a variable lamp load in parallel with each of the H.T. windings of the secondary mesh, the pressure drop on any desired power factor can be determined. In order to prevent

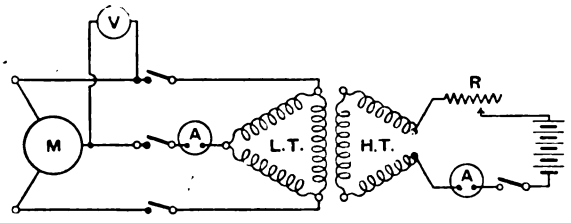


Fig. 3.—Diagram of Connections for Inductive Load Test on a Three-phase Alternator.

any portion of the lamp load current from passing through the battery in this case, the open corner of the mesh is bridged by a carbon rheostat to the middle plate of which one lamp load lead is connected.

In testing alternators for "drop" on inductive loads, it is necessary to take into consideration the wave-form of the current employed for the purpose; for the distribution of the armature reaction over the cycle depends upon this, and it is possible that the "drop," to some extent, depends on this distribution of the armature reaction as well as upon its mean value. A large number of tests were carried out by the author to determine the effect of the above arrangements on the wave forms of both current and E.M.F. of the alternator, and the results of these, as expressed by oscillograph records, were given in the Paper. The conclusion was arrived at that the wave forms were not distorted to a serious degree so long as the currents in the transformer windings were above 25 per cent. of the full-load values for the transformers used. In the case of the test on the three-phase alternator with three transformers, the wave forms were somewhat distorted, but, as shown by the results obtained, this did not appear to have much effect. One of the interesting facts brought out by the oscillograph was that the direct current is thrown into ripples by the superposition upon it of an induced alternating current having twice the frequency of the applied voltage. Another interesting point is that the core losses in the transformers are over four times the full-load loss under normal conditions, so that, as the copper losses are about the same and equal to the normal iron losses, the total losses are about 2·7 times those under normal conditions.

In order to combine the two transformers into one and so save labour in construction, it is suggested that a double magnetic circuit be used, having three parallel cores, of which the middle core has double the section of the outer cores. The primary winding should consist of two equal coils placed upon the outer cores and connected so as to magnetise the rectangle formed by the outer cores and yoke in the same sense. The direct-current winding or secondary should then be placed on the middle core, so that when excited it magnetises the two outer cores in parallel, while it is itself uninfluenced by the alternating magnetic flux produced by the primary windings. By this means half the copper required for the direct-current windings, when two transformers are used, is saved.

DISCUSSION.

DR. W. E. SUMPNER (Birmingham Municipal Technical School), who opened the discussion, considered that the method described by the author was a very convenient one for obtaining low power factors. Methods previously available were the Ayrton copper rings, Swinburne Hedgehog transformer, and the choking coils recently described by Messrs. Morcom and Morris (*see* ELECTRICAL ENGINEERING, Vol. III., p. 427). Some trouble would probably occur in applying the author's method to large machines in view of the fact that the core losses were so great. The temperature rises would be very rapid, and some means would have to be adopted to keep the transformers cool.

MR. S. P. SMITH (Siemens Bros. Dynamo Works, Ltd.) pointed out that the distortion of the current waves disappeared as the current increased, owing probably to the saturation of the core diminishing the effect on the iron. The ripples in the direct-current wave, he said, were probably due to the superposition of harmonics, something on the lines of the action in the case of a machine with a rotating field, where the current in the rotor reacted on that in the stator to produce third or fourth harmonics.

DR. D. K. MORRIS said the test would be most valuable to the engine builder, as no special apparatus would be required. The question of heating due to excessive core losses was not a serious objection, as a quarter of an hour would suffice to take all the measurements necessary to determine the regulation of an alternator on inductive load. One drawback was the need of direct current of very low voltage. An important advantage was the easy adjustment of the power factor with constant voltage; with his type of choking coil it was necessary to put a resistance in series.

MR. A. R. EVEREST (British Thomson-Houston Co.) said that in connection with experiments on the rectification of alternating currents by means of a mercury arc, he had used a high degree of saturation in the core of the transformer, but, as far as he could see, this did not have the effect of largely increasing the core losses and heating. The author in his Paper, on the contrary, showed the losses with high saturation to be much greater than when working round zero flux.

PROF. G. KAPP (Birmingham University) stated that the expense involved in testing an alternator by this method would be nothing like what the use of choking coils entailed. With regard to the heating of the transformer, it should be borne in mind that the hysteresis loss was due rather to the differences in the induction than to the maximum values of the same. It was possible, however, that hysteresis increased with a high degree of saturation of the core. The time taken to raise the temperature of a large oil-cooled transformer was very considerable, even when no allowance was made for the heat radiated or conducted away. Where the heat capacity of such a transformer was very large, he anticipated it would take at least two hours to reach a dangerous temperature. This period would be sufficiently long to determine the voltage regulation, and also form a good idea of the temperature rise of the alternator, which would probably reach its maximum temperature in six hours.

DR. J. D. COALES, in reply, said that Dr. Sumpner's objection to the use of this method for testing large machines had been practically dealt with by Dr. Kapp. Unfortunately, he had only small machines at his disposal, and was unable to carry out the tests on a large scale. His method was capable of being applied to the over-compounding of rotary converters, and this arrangement had, he believed, been patented by someone in America.

CATALOGUES AND PAMPHLETS RECEIVED

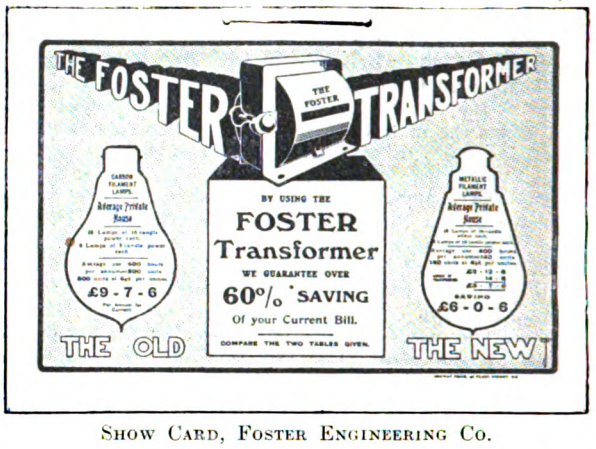
[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering"].

HOISTING APPARATUS, ELECTRIC DRILLS, &c.—Some leaflets from Messrs. Kramos, Ltd., of Bath, illustrate a series of compactly designed electric hoists, transporters, &c., and a special design of lifting magnet, which can be used in connection with this apparatus and also with cranes of larger size. Another leaflet gives prices and particulars of the firm's well-known British-made portable electric drills in sizes suitable for drilling holes from 1/4 in. to 2½ in.

PORTABLE & IGNITION ACCUMULATORS.—A neat illustrated pamphlet is to hand from the Chloride Electrical Storage Co., Ltd., of Clifton Junction, Manchester. In this pamphlet the various sizes of "Exide" accumulators for ignition purposes and for portable lamps are listed. The ignition capacity is reckoned to be twice the capacity on a 10-hour discharge rate; this method of estimating the ignition capacity gives values in accordance with the rating proposed by the Society of Motor Manufacturers and Traders. The cells are fitted with prepared wood separators and have celluloid boxes. Acid-proof carriers of rubber, metal cases, and wooden crates are included in this pamphlet, and hand-lamps with 4-volt 4-c.p. metal filament lamps, and with capacities ranging from 12 to 70 lighting hours on one charge are also listed.

ELECTRIC CRANES.—A handsome catalogue from Messrs. Babcock & Wilcox, Ltd., contains illustrations and particulars of a large range of designs of electric cranes. It will be remembered that the company acquired the business of Messrs. Wimshurst, Hollick & Co., whose electric cranes were well-known, some three years ago, which, while retaining the technical staff of the latter firm, they transferred entirely to their works at Renfrew. Some of the cranes illustrated are of the single-motor type, employing the Hollick patent balanced friction gear, but the largest patterns of multiple-motor crane are also represented. A number of orders are in course of execution for British and Colonial Government Departments, &c.

TRANSFORMERS FOR METAL FILAMENT LAMPS.—The accompanying illustration is a miniature reproduction of an



SHOW CARD, FOSTER ENGINEERING CO.

effective show card, which is being used by the Foster Engineering Co., who were one of the earliest British firms to standardise the manufacture of small transformers for metal filament lamps.

TESTING SETS.—A pamphlet from the India Rubber, Gutta Percha & Telegraph Works Co., Ltd., describes the latest pattern of the small form of the "Silvertown" portable testing set. This consists of a small portable Wheatstone's bridge, together with a suitable galvanometer, mounted on an ebonite slab and fitted into a polished teak case with brass carrying handle. The adjustable resistance contains coils from 1 to 400 ohms, giving a total of 1,110 ohms. The ratio coils are so arranged as to require only two plugs, and by their means ratios of ten times, equality, and one-tenth are obtainable. The range which the instrument can measure is therefore from 0·1 to 11,100 ohms, but by means of galvanometer deflections suitable resistances may be measured to hundredths of an ohm. The galvanometer is fitted with a spring plunger lifting arrangement, so that the pivot and jewel may not get unduly worn or damaged when the instrument is being carried. The galvanometer is calibrated in divisions, which are proportional to the current strengths, and a mirror to prevent parallax error is provided.

POCKET-BOOKS, DIARIES, &c., for 1909.

A clearly printed office wall calendar for 1909, with monthly tear-off sheets, to hand from Messrs. Nalder Brothers & Thompson, Ltd., reminds us of the approach of the close of the present year.

Messrs. Simplex Conduits, Ltd., are sending to some of their friends a very neatly designed circular brass wall thermometer.

Messrs. Siemens Brothers and Co., Ltd., conjointly with Messrs. Siemens Brothers' Dynamo Works, Ltd., are issuing the 1909 edition of their well-known Morocco leather covered pocket book and diary. This season's issue is even more complete than the last, and contains a fund of useful information and a new set of interesting illustrations indicating the wide range of the sphere of action of these two companies.

Our Editor has been much pleased to receive from the Electrical Standardising, Testing, and Training Institution, Faraday House, a compact and convenient "Memory Tickler" in the form of a case containing a card index outfit arranged with guide cards under days of the months.

Accident on the Liverpool Overhead Railway.—A regrettable accident occurred on the Liverpool Overhead Railway on Saturday. The 11.20 p.m. train from Dingle, due to arrive at Seaforth Sands Station at 11.44 p.m. (and arriving eight minutes late), ran with undue speed into the station and came into contact with the hydraulic buffers at the end of the platform. The rails were greasy, owing to the moist weather, and evidently the driver had not applied his brakes soon enough. The front carriage and its occupants were uninjured, the second carriage had some of the windows broken and some of the fittings displaced. One of the passengers unfortunately had her legs broken; all the others escaped injuries. Some complained of being shaken, but were able to walk home. There was no electrical fault, and no interruption of the traffic on the line.

SOME GENERALISATIONS ON THE DESIGN OF ELECTRICAL MACHINERY

THE following communication to the discussion on the Paper with the above title, by Messrs. J. C. Macfarlane and H. Burge (see page 785 of ELECTRICAL ENGINEERING of December 17th), has been received from Dr. R. Pohl, of the Phœnix Dynamo Manufacturing Co., of Bradford:—

This Paper sets out in a very interesting manner the factors that limit the output obtainable from electric machines, and indicates clearly and correctly the present state of design. In so far, however, as it contributes to the theory of the design of electric machines for minimum cost, I do not think that all the conclusions arrived at are correct. A few years ago, in conjunction with H. Bohle, I published such a theory for static transformers, in the design of which the number of variables is, of course, much smaller than in rotating machines, and the problem could be easily solved without any undue assumptions being made. The principle that the total cost for the material of the electric circuit should be equal to the total cost for the material of the magnetic circuit of a transformer was established, and used as the basis of calculation.

The authors of the present Paper go a step further, and apply the same principle to the design of rotating machines and particularly to D.C. machines, and they conclude that the cost of the material in the electric circuit, *i.e.*, of the armature and inter-pole copper, should be equal to the cost of the material in the electric circuit—*i.e.*, of the total iron and the shunt copper. This result is entirely different from present-day practice, and, in my opinion, also far from being correct for the design theoretically most favourable. It is arrived at chiefly by the assumption that the material in the magnetic circuit—that is, the iron and shunt copper—varies directly with the total magnetic loading, which I do not think is really the case. It will easily be seen that with an increase of the magnetic loading the amount of shunt copper by no means rises in proportion to the increase, and as it forms an important part of the total cost, this fact greatly affects the result. Furthermore, even in inter-pole machines a certain relation should be maintained between the field ampere-turns for gap and teeth, and the armature ampere-turns beneath the pole arc, in order to keep the field distortion within permissible limits. As a result, with an increase of the magnetic loading and consequent decrease of the armature ampere turns, the shunt ampere-turns, and also the weight of shunt copper, may sometimes even be made to decrease.

Some years ago, when with the introduction of inter-poles a theory of design for minimum cost without regard to sparking became of practical interest, I worked out a suitable method from which I concluded that in the most favourable machines the ratio of the cost for armature and inter-pole copper to the cost for iron and shunt copper is not constant for all sizes, and is generally between $\frac{1}{4}$ and $\frac{1}{3}$. Another conclusion was that the length of the armature core should be considerably greater than the pole arc, and not equal to it, as the authors assume. The curves are, however, very flat, and one may depart very considerably from the point theoretically most favourable without adding appreciably to the cost of the active material. Such departure is generally desirable, because, after all, the cost of the active material is not the only point to be kept in mind in the design of a machine. Though differing from the authors in some of the points cited above, I have read the Paper with the greatest interest, and cannot refrain from congratulating them on the clear manner in which they have given so much detailed information of real practical utility in, comparatively, so short a Paper.

LOCAL NOTES

ALTRINCHAM: *Tramway Lease.*—Notice is given of the intention of the Council to lease to the Manchester Corporation, for 23 years, five authorised tramways, the lease to be reckoned as from May 10th, 1907.

BIRKDALE: *Public Lighting.*—A number of high candle-power Osram lamps are being fitted in the streets as an experiment in public lighting, owing to the number of breakages when carbon filament lamps were used. Trials are also to be carried out with arc lamps in the more important thoroughfares. These experiments are being carried out by the Birkdale Electric Supply Co. at the instance of the Council.

BIRMINGHAM: *Tramwaymen's Hours.*—The Tramways Committee have adopted the report by Mr. A. Baker, the Tramways Manager, by which a 54 hour week has been adopted for the whole of the present tramway staff, without a reduction in pay, instead of the 60 hour week at present in force. New members of the staff, however, will commence at a slightly reduced wage and reach the maximum in six years instead of four as at present.

BRENTFORD: *Condition of Tramway Track.*—At the last meeting of the Council the chairman reported that he had attended the conference at Hounslow with respect to the condition of the tracks of the London United Tramways Co., at which Sir Clifton Robinson attended and spoke. The chairman stated that the representatives of the various districts were determined to keep Sir Clifton Robinson up to the mark, and with that object in view a resolution was passed at the conference that the surveyors of the different districts should meet Sir Clifton Robinson and go over the tracks in the respective districts and to submit detailed reports to a further conference at which Sir Clifton Robinson is again to be invited to attend.

CHELTENHAM: *Cost of Public Lighting.*—In his annual report the District Auditor calls attention to the charge for public lighting, viz., 3d. per unit, which he considers excessive.

DUBLIN: *Damages Against Tramway Co.*—The sum of £500 damages has been awarded against the Dublin United Tramways Co. in connection with the death of a painter who was thrown out of a cart through a wheel catching in a rut next to the tramline. It was argued that this was due to the negligence of the tramway company to maintain their track in proper condition.

DUNDEE: *Stair Lighting.*—A proposal that the electricity department should bear the cost of the wiring and fitting of common stairs, in order to induce the proprietors to take current, has been referred back.

Gift of Electric Light Installation.—Sir William Dalgleish, Bart., has borne the complete cost of an electric light installation at the Dundee Sailors' Home.

FALMOUTH: *Overhead Wires.*—The Electric Supply Corporation have been granted permission to erect some overhead wires to supply the district where the possible load does not justify the laying of a cable.

GLASGOW: *Tramway Receipts.*—Since the commencement of the financial year on June 1st, 1908, the number of passengers carried upon the Corporation Tramways has amounted to 119,964,000 against 121,631,946 in the corresponding period of last year, the respective receipts being £480,766 and £489,322.

GOVAN: *Plant Extensions.*—A sub-committee has been appointed to enquire into a report upon the extensions to the Electricity Works. The Borough Electrical Engineer has drafted two schemes involving respective expenditures of £14,000 and £11,000.

HENDON: *Public Office Lighting.*—The Hendon Electric Supply Co. offered to supply the necessary fittings for lighting the Council offices with electricity. The surveyor is to furnish a report giving particulars of the present cost of lighting the premises and the saving which would be effected by adopting the electric light.

LEEDS: *Tramway Receipts.*—The total receipts upon the Corporation tramways for the year to date amount to £244,543, compared with £241,070 for the corresponding period of 1907.

LONDON: *London County Council Tramways.*—In consequence of the opposition to the proposed tramway along Sutherland-avenue, Paddington, the Highways Committee recommend that this route be struck out of the list of proposed tramways for the session 1909.

The arrangement between the County Council and the Metropolitan Electric Tramways, Ltd., providing for the Council's tramway in Archway Road between the Archway Tavern and the county boundary to be worked by the company has terminated, and the Highways Committee recommend that the arrangement be extended up to and including March 31st, 1909. The rent to be paid to the Council by the company is at the rate of £2,500 per annum.

It is proposed to deal with an additional 52 cars during the current financial year in connection with the alteration from the "reversed" staircase to the "direct" type, in order to bring them into conformity with the bye-law made by the Council for the purpose of requiring an uninterrupted side view for drivers of vehicles in London. The expenditure is estimated at about £370.

The Board of Trade inspection of the new line at Forest Hill was made last week.

Marylebone Consulting Engineer's Fees.—In a report by the Electric Supply Committee, it is stated that the total commission paid to Mr. Arthur Wright for his services as consulting electrical engineer now amounts to £25,209.

Digitized by Google

LYME REGIS: *Electric Lighting.*—A proposal to form a Lyme Regis Electric Light and Power Co. is now before the Council.

MACCLESFIELD: *Electric Supply.*—After consideration, the Corporation has decided to retain its electric lighting order, and to refuse its consent to an application by the Macclesfield Electric Lighting and Power Co., for a substituted order.

MIDDLESBROUGH: *Trackless Trolley System.*—Some difficulties are being experienced between the Corporation and the Middlesbrough, Stockton and Thornaby Tramways Co., as to certain extensions, and as a way out of the difficulty the trackless trolley system has been suggested. The Electrical Engineer to the Corporation has been instructed to obtain comparative particulars of the cost of the trackless trolley system and an extension of the tramways for the information of the General Purposes Committee who have the matter in hand.

MIDDLESEX: *Tramways.*—It was reported at the meeting of the County Council on December 17th that the Metropolitan Electric Tramways, Ltd., are negotiating with the London County Council for a continuance for a further period of the agreement under which the Spring Gardens authority at present leases the short length of tramway from the Archway Tavern to Highgate Archway to the company.

ROCHESTER: *Public Electric Lighting.*—An estimate has been submitted to the Works Committee of the cost of substituting electric lighting in the High-street for the present gas lamps. It is calculated that 54 arc lamps should take the place of the present 52 gas lamps. The figures of cost, however, show that if "Excello" 3,000 c.p. lamps are fixed the total annual cost, including repayment of principal and interest, would be £763 against £163 of the present gas lighting, whilst if "Excello" 2,500 c.p. lamps are fixed the cost would be £712. If "Oriflamme" 3,000 c.p. lamps are fixed the cost would be £564. In view of the great disparity between these figures and the present cost of gas lighting, the Council has decided to abandon the idea of the change for the present.

SOUTH AFRICA: *Electric Lighting.*—We read in *South Africa* that the Town Council of Uitenhage has accepted provisionally the electric lighting scheme of the General Electric Co., of London. The matter has still to come before the ratepayers for approval.

TEWKESBURY: *Electric Supply.*—The plans of the electric supply works have been passed.

TOTTENHAM: *Electric Lighting.*—It has been agreed between the Council and the North Metropolitan Electric Power Supply Co., to defer the electric lighting in the district, in order to save the expenditure this half-year. Under the agreement of January 15th, 1907, the Council agreed to light 110 arc lamps for a period of eleven years from the date thereof, and as the company were about to commence the supply they agreed to defer it until the end of March, in consideration of the Council extending the lighting period for a further three months at the expiration of the above term. The company now asked the Council to pass a resolution to this effect, and the Committee recommended the Council to accede to the request. This was agreed to.

WELLS: *Electric Lighting.*—A discussion took place at the last monthly meeting of the Council relative to the application of the local gas company for electric lighting powers. After a proposal to oppose had been moved, the matter was referred back to the General Purposes Committee.

WISHAW: *Tramway Extensions.*—Plans of the proposed extension of the Lanarkshire tramways to Wishaw are now in the hands of the Council, and it is expected the work will be started during the next few weeks, and that it will be completed by the end of March next.

WOLVERHAMPTON: *Tramway Inter-communication.*—The Tramway Committee have reported in reference to the letter from the Tramway Co., notifying their intention of discontinuing the through service upon their trolley tramways and the Corporation surface contact tramways. The report points out that the Committee have no suggestions by which the matter can be re-opened, and acknowledges the effort which the Company has made to make the arrangement a success.

WORSBOROUGH: *Tramway Rating.*—Under the recent decision that light railways are to be treated as railways for rating purposes, *i.e.*, should be rated upon one-fourth the assessment. The undertaking of the Barnsley Electric Traction Co. in Worsborough is now dealt with in this manner. An application, however, has been made to the Council for the return of the sum of £55 10s., which the company claim to have been overcharged in the past. The Town Clerk has expressed the opinion that, from the legal point of view, the company cannot recover, but that there was some obligation on the Council, from the moral point of view, to return the money. The Local Government Board is to be asked whether it will give permission for this to be done.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ALGERIA.—The Municipality of Bone has postponed the date for receipt of tenders for an electric tramway and lighting concession until February 15th, 1909. We gave particulars of this in our issue for December 3rd

CLEETHORPES.—The Council has applied to the Local Government Board for sanction to borrow £4,000 for cables in connection with their electric lighting order.

CROYDON.—It has been decided to lay a two-way conduit to carry the new feeder cable from the power-house to the Swan feeder pillar at a cost of £1,321.

EPSOM.—A Local Government inquiry was held last week into the application by the Corporation to borrow £1,500 for purposes of electric lighting. The inquiry was adjourned for the preparation of certain information for the inspector.

FAREHAM.—The Council invite tenders for (1) three alternators and exciters; (2) high- and low-pressure switchboard; (3) overhead travelling crane. Particulars from the Consulting Engineers, Messrs. May & Hawes, Caxton House, Westminster, London, and tenders to the Town Clerk, by January 20th.

FROME. The Local Government Board has sanctioned the expenditure of £11,000 upon electric lighting extensions.

GRAVESEND.—The Local Government Board held an enquiry last week into an application by the Corporation for sanction to borrow £6,000 for the purposes of the electric lighting undertaking.

INDIA.—*Commercial Intelligence* states that the British Eastern Electric Power Co.'s concession for the introduction of electric light and traction in Lucknow having expired, the Municipality of Lucknow have decided to invite tenders by public advertisement for the lighting of the town by electricity, and by gas. The Municipality has asked the Government whether it could undertake the management of a municipal plant.

We read in *Commercial Intelligence* the United Provinces Government have granted a licence to the Municipal Board of Mussoorie for the general supply of electrical energy in respect of the area comprised within the Municipal limits of Mussoorie.

LEITH.—A 600-kw. steam dynamo is required by the Corporation. Particulars from the Borough Electrical Engineer, and tenders by January 6th.

LONDON: *Battersea.*—The Finance Committee of the London County Council recommend loans as follows:—Mains £2,090, repayable in 30 years; house services £778, repayable in 12 years.

Marylebone.—The Finance Committee of the London County Council recommend sanction to a loan of £4,426, repayable in 50 years, for alterations to the Aybrook Street sub-station.

Woolwich.—The Finance Committee of the London County Council recommend sanction to the borrowing of £753, repayable in 20 years, for the construction of a cooling pond in connection with the electric lighting undertaking.

SOUTHAMPTON.—The three alternating machines in use at the works being nearly fully loaded with the existing demand, the electrical engineer points out in a report on the matter that a new motor alternator would cost £700, which could be operated from the existing generator, and would be the most economical method of dealing with the day load machines. The Council has decided to adopt the engineer's advice.

SPAIN.—The Castro del Rio Municipality invites tenders for an electric lighting concession during a period of 20 years. The annual rent asked is £214.

WEDNESBURY.—The Local Government Board has sanctioned a loan of £600 for an overhead feeder to the King's Hill District.

Miscellaneous

ARGENTINE.—The *Review of the River Plate* states that the Santa Fé municipality will shortly call for tenders for the electrification of the tramways. The basis of the contract will be the sale of the present municipal lines.

BECKENHAM.—Tenders are invited for electricity meters. Particulars from the Resident Engineer, and tenders to the Town Clerk, by January 4th.

BELFAST.—Tenders are invited by the Belfast Harbour Commissioners for the supply of 100 tons of best rolled steel girder tramway rails, with fish plates and bolts. Particulars from the Harbour Engineers, and tenders by December 30th.

MEXICO.—A contract has been concluded between the Mexican Government and the Cia de Tranvias de Mexico, S.A., for the construction of tramways in Mexico.

MIDDLESBROUGH.—Tenders are invited for the supply, delivery, and erection of 20 flame arc lamps, posts, brackets, and incandescent fittings for same. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk, by December 30th.

PORTSMOUTH.—Tenders are invited for overhead line material, &c., in connection with the construction of the Gold-

Digitized by Google

smith Avenue Tramway. Particulars from the Tramways Engineer, and tenders to the Town Clerk, by January 4th.

RUSSIA.—Conditions relating to the Baku electric tramway concession, which was noticed in our issue for December 3rd, may be seen at the Commercial Intelligence Branch of the Board of Trade.

The *Financial News* St. Petersburg correspondent states that there is a great future for electrical enterprise in Russia. The satisfactory results obtained by the electrical undertakings in St. Petersburg, Moscow, and other towns have stimulated a number of municipalities to substitute electrical for horse tramways. Odessa, Kharkov, Vilna, Baku, and Astrakan, especially, are pushing forward in the matter.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—Adaptation of St. Cecilia's House, Commercial Road, as a domestic economy centre (£260). T. J. Bailey, Architect to the L.C.C. Education Committee.

E.C.—Addition to *Times* printing offices, 162 Queen Victoria Street. Architect, H. O. Ellis, 46 Fenchurch Street, E.C.

Alterations for additional office accommodation for L.C.C. tramways department at Evelyn House, Finsbury Pavement (£250). W. E. Riley, architect.

Rebuilding Bell's Buildings (£21,800). Architect, F. W. Forster, 41 Bedford Row, W.C.; builder, J. S. Minter, High Street, Putney.

N.—Adapting disused Fire Brigade station at 38 Seven Sisters Road, for commercial purposes. Surveyors, Gilbert & How, 5 Crouch Hill, Hornsey, N.

N.E.—Assembly Hall, Stanboroughs Yark, rear of High Street, Kingsland. Builders, G. E. Wallis & Sons, Ltd., West Street, Bethnal Green.

N.W.—Proposed new infirmary and phthisis wards, &c., Hendon. Clerk to Hendon Board of Guardians.

Club room, Town Square, Hendon, Hampstead Garden Suburb Architect, E. L. Lutyens, 29 Bloomsbury Square, W.C.

S.E.—Fire station in Foxley Road, Camberwell New Road (£7,450). Contractors, John Barker & Co., Ltd., 83 Kensington High Street, W.

S.W.—Photographic studio at 298 Streatham High Road. Builders, A. J. and C. Hocking, 56 Great Queen Street, W.C.

W.—Extension to Technical Institute, Paddington (£8,200). Contractors, E. Lawrance and Sons, Wharf Road, City Road.

PROVINCES.

ABERDARE (GLAM.).—School. Architect, T. Roderick, 23 Clifton Street.

BARNSTAPLE (DEVON).—New Infant School. G. W. F. Brown. Clerk to the Education Committee, Barnstaple.

BRISTOL.—Mission Church, School, etc., Kingswood (£4,000). Architect, J. Mackay, Kimberley Road, Kingswood, Bristol.

CANTERBURY.—Extension to City School of Art. A. C. Turley, Surveyor to Town Council.

CHISLEHURST.—Enlargement of Council Chambers. W. J. Winter, Surveyor to Urban District Council.

CHRISTCHURCH (HANTS).—Proposed addition to workhouse. Architect, c/o Clerk to the Guardians.

CROYDON.—Additions to Stanley Hall, South Norwood Hill, for W. F. Stanley, Optical Works, South Norwood.

Entertainment hall, North End. Architect, A. Broad, 22 George Street.

Isolation hospital (£7,370). J. S. Killick, Surveyor to Rural District Council.

EPSOM.—Enlargement of technical institute. Ramsay Nares, Secretary, Surrey Education Committee, Kingston.

GLASGOW.—Development of Cardonald estate. A. B. M'Donald, Engineer to Glasgow Corporation.

HARROGATE.—Infant school at Bilton School (300 places). J. Turner Taylor, Clerk to the Education Committee.

LEYTON.—School, Sybourn Street (£10,650). Builder, F. J. Coxhead, Bulmer Road, E.

Additions to municipal offices (£8,500). Builder, North Bros., Stratford, E.

LUTON.—Free library. S. F. L. Fox, Borough Surveyor, Luton.

NEATH (GLAM.).—Swimming baths. Mr. Jenkins, architect, Guildhall, Neath.

NORTHALLERTON.—Proposed isolation hospital. W. Watson, Surveyor to the Urban District Council.

NORTHAMPTON.—Additions to hospital (£7,000). Architect, F. Dorman, 5 Mercers' Row.

PENNYCROSS (PLYMOUTH).—Church of St. Martin. Architect, W. D. Caröe, 3 Great College Street, S.W.

PLYMOUTH.—Swimming and Turkish baths (£6,000). Architect, E. Coath Adams, 20 Bedford Street.

RUGBY.—Opera House. Architect, H. Percival, 47 Mortimer Street, London, W.

SHIPLEY.—By the casting vote of the Mayor, the Saltaire Institution is to be lighted electrically.

SHREWSBURY.—Proposed "Walsham How Mission House" (estimated cost, £3,000). Secretary, the Rev. A. E. Ll. Kenyon, rector of Ludlow.

SOUTHAMPTON.—Chapel and lodge. J. A. Crowther, Engineer, Southampton Town Council.

SWANSEA.—Infants' school, Brynmill, and school at Glanmor. Architect, G. E. T. Laurence, c/o Town Clerk.

Gymnasium, cookery class-room, &c., for Higher Girls' School. A. W. Halden, secretary, Swansea Education Committee.

Asylum. Engineer, R. H. Wyrill, Swansea Town Council.

Rebuilding Masonic Hall, Caer Street.

Art Gallery (£12,000). Architect, Glendenning Moxham, Castle Street.

TAUNTON.—Post Office. H.M. Office of Works, Storey's Gate, S.W.

WATFORD.—New Baptist Church, Leavesden Road, for the Trustees, Leavesden Road Baptist Church.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The New South Wales Postmaster-General's Department has accepted the tender of the Western Electric Co. (Australia) Ltd., for the supply, delivery, and erection of a branching metallic multiple magneto switchboard, at Mosman, at £3,346, with additional cabling to the extent of £58, and apparatus for twenty-seven incoming junction lines, at 24s. 6d. each, and for forty outgoing junction lines, at 11s. 6d. each.

BELFAST.—The tender of the British Insulated & Helsby Cables, Ltd., has been accepted for trolley wire.

CARDIFF.—The tender of Mr. C. Pullan, of Bradford, has been accepted for the installation of electric lighting in the Cardiff Museum at £76.

CROYDON.—The Corporation have accepted the tender of W. J. Bishop & Co., Croydon, at £59, for electric wiring and fitting at the department's inquiry office and store (3 Park Lane). The maintenance contract with the Tudor Accumulator Co. for one battery has lapsed, and the contract for the second will lapse in the spring. The amount paid per annum for the two batteries is £58. It was resolved to extend the contract for five years at the increased rate of £65 per annum.

DARLINGTON.—An order has been placed with Messrs. Cox-Walkers, of Darlington, for an electrically-driven pump.

LONDON: *London County Council.*—The following tenders have been received for the electric lighting of the Clapham Secondary Schools:—G. E. Taylor & Co. (recommended), £699; W. J. Fryer & Co., £747; Aland & Co., £783; Comyn Ching & Co., £786; W. G. Cannon & Sons, £789; G. Weston & Sons, £803; Tredegar & Co., £923; G. N. Haden & Sons, £971; S. J. Suter & Wood, £987; Lund Brothers & Co., £990; F. C. Hoskins & Co., £1,084; C. Pullan, £1,116. The original estimate of the chief engineer, amounting to £1,055, was based on the use of carbon filament lamps, whereas the scheme on which tenders were invited provides for the use of metallic filament lamps, which enables a reduction to be made in the number of points to be provided and an improvement to be effected in the lighting, together with economy in the consumption of energy.

The Highways Committee recommend that the contract with Messrs. W. T. Henley's Telegraph Works Co., Ltd., for the supply of low-tension cables for the central car repair depôt, shall be extended to include the telephone installation at a cost not exceeding £125.

The offer by Messrs. Hadfields' Steel Foundry Co. to supply a right-hand standard junction, consisting of points, track, and slot crossing, yokes, &c., at the Hackney car-shed, at £262, less 2½ per cent., has been accepted.

An offer by Messrs. John Cochrane & Sons for the provision of additional condensing water-pipes at the Greenwich power house at cost price, plus 10 per cent., is recommended for acceptance. The estimated cost is £8,000.

Chelsea.—The Council have accepted the tender of Messrs. Wright Bros. & Co., at £23 17s. 6d., for putting the electrical installation in the old portion of the Town Hall in repair. They have further accepted the tender, at £35 7s. 6d., of the same firm for alterations to the electrical installation at the new portion of the Town Hall. The work consists of supplying and fixing six distributing fuse boards, altering the position of the main cable in the basement, and connecting same to new main distributing fuse board.

Marylebone.—The Council received tenders for the supply of paper-insulated, lead-covered, and armoured cable from the following firms, viz.:—Aubert, Grenier & Co., Union Cable Co., Ltd., Siemens, Bros., Ltd., Western Electric Co., Johnson & Phillips, Ltd., St. Helens' Cable Co., Ltd., Callenders' Cable Co., Ltd., W. T. Glover & Co., Ltd., Blackwell & Co., Henley's

Digitized by Google

Telegraph Works Co., Ltd., British Insulated & Helsby Cables, Ltd., and Lahmayer Electric Co. It was explained that tenders from foreign firms had been invited owing to a combination among British firms to keep up prices. Upon the recommendation of the Electric Supply Committee the Council accepted the lowest prices in the tenders of Messrs. Aubert, Grenier & Co. and the Union Cable Co., subject to the samples proving up to specification standard, these prices amounting to £500 less than the lowest prices of the British firms. The detailed prices per 220 yards of the successful firms were as follows:—Union Cable Co., S.W.G., single, 7/18, £4 5s. 4d.; 7/16, £7 5s. 3d.; twin 3/20, £7 11s.; armoured, 7/20 five-core, £18 6s. 9d.; 0·50 sq. in. concentric, £26 5s. 1d.; triple concentric, 0·025 by 0·025 by 0·025, £27 17s. 10d.; 0·050 by 0·050 by 0·035, £37 19s. 6d.; 0·4 by 0·4 by 0·15, £162 15s. 7d.; 0·5 by 0·5 concentric, £149 13s. 10d. Aubert, Grenier & Co., S.W.G., 7/20, five-core, £13 12s. 5·8d.; concentric, 0·025 sq. in. £10 9s. 2d.; 0·050 sq. in., £21 3s 8d.; 0·5 by 0·5, £135 18s. 6d.; triple concentric, 0·025 by 0·025 by 0·025, £20 12s. 8d.; 0·050 by 0·050 by 0·050, £30 5s. 10d.; 0·1 by 0·1 by 0·05, £46 5s. 6d.; 0·15 by 0·15 by 0·075, £64 4s. 10d.; 0·25 by 0·25 by 0·125, £94 2s.; 0·4 by 0·4 by 0·15, £142 2s.; 1 sq. in., single, £131 15s. 6d.; armoured, 7/20, five-core, £17 3s. 2d.; triple concentric, 0·1 by 0·1 by 0·05, £57 5s. 6d.; 0·15 by 0·15 by 0·075, £76 4s. 10d.; 0·25 by 0·25 by 0·125, £108 2s.; 1 sq. in., single, £144 15s. 6d. The tenders of Messrs. Doulton & Co., Ltd., and the Albion Clay Co., Ltd., have been accepted for ducts and troughing.

Poplar.—The tender of Messrs. W. G. and J. H. Nash has been accepted for carrying for ventilating purposes the two existing openings in the battery room floor of the engine room through the roof of the building by means of galvanised iron shafts with louvre and cowl at a cost of £25.

WOLVERHAMPTON.—The Electricity Committee has accepted the tender of the Electric Construction Co. for switchgear and accessories at £120, and the fittings for forced ventilation to two turbo-alternators at £250.

COMPANIES' MEETINGS AND REPORTS

ADELAIDE ELECTRIC SUPPLY CO.—The report for the year ended August 31st, 1908, states that with the sanction of the holders of the preference and ordinary shares, a further 6,000 preference shares of £5 each were issued in April and May last, the whole of which were again applied for by and allotted to the public in Adelaide. The profit and loss account shows a credit balance for the year of £12,962. After payment of the dividend on the preference shares for the half-year ended February 28th, 1908, writing £606 off suspense account (consisting of the cost of the various issues of preference shares), and placing a sum of £1,000 to depreciation account, there remains, including the amount carried forward from the previous year, an available balance of £9,330, which the directors recommend should be applied as follows:—Dividend on six per cent. preference shares for the half-year ended August 31st, 1908; 3½ per cent. dividend on ordinary shares for the year ended August 31st, 1908; balance carried forward, £879.

ANGLO-ARGENTINE TRAMWAYS CO.—At a special meeting of share and debenture holders on Friday, the resolutions were passed dealing with the re-arrangement of the company as follows:—To exchange the existing £266,600 of 6 per cent. debenture stock for 4 per cent. debenture stock, ranking *pari passu* with the 4 per cent. debenture stock already issued, at the rate of £155 of 4 per cent. stock for £100 of 6 per cent. stock; to exchange the £1,300,035 of 6 per cent. cumulative first preference shares for a new issue of 4½ per cent. debenture stock, redeemable in 75 years, and ranking immediately after the 4 per cent. debenture stock, at the rate of £6 13s. 4d. of 4½ per cent. stock for each £5 first preference share, thus giving the holder the present rate of interest—namely, 6 per cent. per annum; to increase the authorised amount of the 10 per cent. non-cumulative second preference shares of £5 each by £400,000, and to convert each of the existing and new second preference shares of £5 each into two 5 per cent. cumulative first preference shares of £5 each, entitled to one vote per share. After the second preference shares have become first preference shares, to convert the existing third preference shares into second preference shares, with the same rights as at present. It was pointed out at the meeting that the Corporation of Buenos Ayres has granted its permission to the fusion of the various tramway interests in the City upon certain conditions, including the handing over of the whole of the undertaking at the termination of the concession, gratuitously, and the construction of 20 kilometres of new lines within the next 20 years.

COSTA RICA ELECTRIC LIGHT & TRACTION CO.—For the year ended June 30th, 1908, the revenue amounted to £14,402 against £14,303 for the previous year. After meeting expenses and debenture interest, there is a net profit of £4,490, compared with £3,961 last year. This surplus is to be applied to the sinking fund and the reduction of discount on debenture issue account.

ELECTRIC CONVERSION SYNDICATE.—The report for the year to September 30th states that during that period the Board has been principally engaged in liquidating the amounts due to secured creditors, the amount of whose debts on September 30th amounted to £7,642. This amount, however, has been further reduced since the closing of the books.

PROVINCIAL TRAMWAYS CO.—The report for the year ended September 30th states that the net revenue received from the local companies has been £33,084, against £38,049 last year, £30,993 in 1906, and £24,050 in 1905. Adding amount brought forward and transfer fees, there is a balance available of £36,749. From this has to be deducted: Administration expenses, vote to directors at last meeting, income tax—balance of account, interest, interest to debenture holders paid and accrued, preference dividend, interim dividend on ordinary shares, £20,206, leaving £16,543. From this sum the directors have set aside for reserve and depreciation the sum of £8,000, and have also written off £500 from the expenses of the issue of the debenture stock (making, with £3,000 reserved last year, the sum of £3,500 written off), and after these deductions the amount at the disposal of the directors will be £8,042. The directors recommend that a dividend be paid upon the ordinary shares of 4s. per share, making, with 3s. per share paid in June last, 7s. per share, free of income tax, for the year. There will then be a balance to be carried forward of £3,060. In common with other tramway concerns, the traffic receipts have been reduced by general depression in trade and bad weather during the best months of the financial year. This has caused a decrease in the net revenue of the local companies. At the meeting on Friday the report and accounts were adopted.

SHANGHAI ELECTRIC CONSTRUCTION CO.—At the annual meeting, on Friday, the report and accounts were adopted. Sir A. Dent, K.C.M.G., who presided, referred at some length to the negotiations with the municipality of Shanghai for the purchase of the undertaking which had been rejected by the ratepayers in 1907. No further progress had, he said, been made in this direction, the negotiations having been practically suspended pending the solution of other more important matters appertaining to the administration of the company. Amongst these, the question of fares taking a leading position, the company having demonstrated by their experience that they could not earn an adequate profit upon the present basis of fares. A new table of fares and distances was now before the Council, and he hoped it would meet with their approval. At the same time, he thought greater latitude should be left to the company in this direction subject to interference by the Council should the requirements of the public not be adequately met.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON.—At the annual general meeting on Monday, the report and accounts given in our last issue, were adopted. The chairman, Sir Edgar Speyer, said that hitherto the accounts of the company had been made up annually to the end of June and the general meeting had been held in the autumn. In future, however, the revenue account would be made up half-yearly to June 30th and December 31st, and in the opinion of the directors it would be convenient to hold the meetings in February and August, and in February next the proprietors would have submitted to them a balance-sheet made up to December 31st next, with a revenue account from the close of the liquidation to the end of the year. The conversion scheme had been carried through without a hitch, and the Prior Lien bonds had been successfully issued. The increase in traffics had been satisfactory, both on the District Railway and on the tubes.

UNITED ELECTRIC TRAMWAYS OF MONTEVIDEO.—At an extraordinary general meeting on Monday, resolutions were passed increasing the capital from £800,000 to £1,000,000 by the creation of 20,000 further 6 per cent. cumulative preference shares of £5 each, ranking *pari passu* with the existing preference shares, and 20,000 further ordinary shares of £5 each, ranking *pari passu* with the existing ordinary shares. Resolutions were also submitted to a meeting of the debenture-holders for an issue of £200,000 further 5 per cent. debenture stock.

Mr. George A. Touche, the chairman of the company, who presided, stated that the need for extra capital was the extraordinary rapidity with which their business had been expanding. They had estimated traffic receipts of £255,000 during the first complete year of electrification, but, as a matter of fact, although a year's electric working had not yet been completed, their receipts had amounted to £252,758. In addition to 77¼ miles of track at present in operation, a further 3¾ miles was expected to be finished during the next few months. Their early financial requirements amounted to something like £107,900. Orders had been placed for additional plant for the power-house to the extent of £52,200, and there were very considerable prospective requirements for rolling stock, permanent way, and paving.

Digitized by Google

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f., port of arrival, quoted on Tuesday night, was £65 to £65 10s. per ton (last week £65 10s. to £66 per ton).

DISSOLUTIONS OF PARTNERSHIP.—The partnership between T. H. Satchwell and A. E. Gibbings, trading as Satchwell and Gibbings, Tantarra Electrical Works, Tantarra Street, Walsall, has been dissolved.

The partnership between J. W. Revy and P. F. Besch, trading as electrical engineers under the title of Revy, Phillips and Co., at 181, Queen Victoria Street, London, E.C., has been dissolved.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A meeting of creditors in the bankruptcy of Thomas Ward, late director of Electric Instruments Manufacturers, Ltd., Freezywater, Waltham Cross, Herts, was held last week for considering a proposal for the payment of a composition of 7s. 6d. in the pound within six months. The proposition has been accepted.

Mr. L. B. Linnett, 42, Poultry, London, E.C., has been appointed trustee in the bankruptcy of W. J. Aubert, electrical and gas engineer, late of 16, Harp Alley, London, E.C.

A meeting of creditors of the Aluminium Corporation, Ltd. (in liquidation) was held yesterday.

A second and final dividend of 7½d. in the £ will be paid on December 29th at the Official Receiver's office, 13 Winckley Street, Preston, in the bankruptcy of R. S. Blackburn, electrical engineer and contractor, of Hebden Bridge, Yorkshire.

SOME RECENT B.T.H. MINING CONTRACTS.—The extent to which electricity is being applied for mining and for power purposes generally, is well exemplified in the following list of the more important motor installation contracts which were secured by the power and mining department of the British Thomson-Houston Co., during 1908:- Carlin How Mines, Durham: 5 three-phase motors, 6½ to 175 h.p., aggregating 321½ h.p., together with controllers, switchgear, mechanical gearing, emergency brake and three-throw ram pump. Sheffield Coal Co.: 1 250-kw. A.C. generator, 7 three-phase motors, 30-80 h.p.; total, 320 h.p.; controllers, resistances, transformers, and switchgear. Joshua Whiteley and Co., Ltd., Albion Mills, Huddersfield: 23 three-phase motors, 6-55 h.p., totalling 928 h.p., together with switchboards, control panels, necessary wiring, etc. J. and P. Coats, Ltd., Glasgow: 8 three-phase motors, 300-325 h.p., total 2,600 h.p., with controlling gear, panels, etc. Pease and Partners, Darlington (for Esh Colliery): 1 125-kva generator, 1 45 h.p. and 1 70-h.p. motors (total 115 h.p.), with switchboard, controllers and resistances, also two 15-25-h.p. motors, total, 40 h.p.; control panels, etc.; also 2 25-120-h.p., 145-h.p. motors, 1 130-kw. transformer, controllers, resistances and switchgear. Fife Coal Co., Leven: 19 three-phase motors, 25-50 h.p. = 660 h.p., with controlling gear. Aveling and Porter, Ltd., Rochester: 8 three-phase motors, 2¼-16 h.p. = 105¾ h.p., with stg. rheostats, wiring, etc. London Corporation (for Central Criminal Court): 8 8-h.p. = 64 h.p. D.C. motors, with starters and panels. Gwynnes, Ltd.: Testing plant for Borough of Hammersmith—1 120-kv. motor generator set, 1 110-kva. type A.B.T. generator, 1 146-h.p. motor, 1 10-kw. exciter, 1 140-kw. transformer, with switchgear. Greeves, Ltd., J. and T. M., Fort River Mills, Pelfast: 8 three-phase motors, 2-60 h.p. = 92 h.p., with switchgear. Glenboig Union Fire Clay Co., Ltd., Glenboig, N.B.: 20 three-phase motors, = 1,225 h.p., with controllers, resistances, panels, etc.

APPOINTMENTS AND PERSONAL NOTES

The South Indian Railway Co. require an electrical engineer to take charge of the electric lighting and electric driving installation in the company's locomotive shops. Candidates must be between 25 and 35 years of age, and must have had an electrical and mechanical engineering training. The salary is Rs.500 per month, rising annually by Rs.50 to Rs.700 per month. The engagement is for five years. Applications to Mr. R. White, consulting engineer to the company, 3 Victoria Street, London, S.W.

The *Review of the River Plate* states that Mr. P. W. Beatty, chief electrical engineer to the Pacific Railway Co., has returned to Buenos Ayres from a business trip to England.

Lieut.-General Sir Richard H. Sankey, K.C.B., who was a director of the Cleveland and Durham County Electric Power Co., and Deputy-Chairman of the South Wales Electrical Power Distribution Co., and who died in November, left estate of the gross value of £2,447.

The Institution of Civil Engineers: Students' Meeting.—At the students' meeting, held at the Institution on Friday, December 18th, at 8 p.m., Mr. E. P. Hill, M.Inst.C.E., in the chair, the Paper read was "High-power Water Turbines on Moderate Falls," by R. Woldenden, M.Sc. The Paper, which was illustrated by lantern-slides, described briefly the various types of impulse and reaction turbines and their regulation, and discussed mathematically the design of mixed flow and radial inward-flow turbines.

MISCELLANEOUS CITY NOTES

AMERICAN TELEPHONE & TELEGRAPH CO.—The regular quarterly dividend of $2 per share has been declared.

COMPANY TO BE STRUCK OFF REGISTER.—Notice is given in the *London Gazette* that the name of the British Blaknik Arc Light Co., Ltd., will be struck off the register of Joint Stock Companies within three months, unless cause is shown to the contrary.

GALLOWAYS.—At the last board meeting, resolutions were passed authorising the postponement of the payment of the balance of preference dividends for this or any future year until after the general meeting.

LIVERPOOL ELECTRIC CABLE CO.—At the ordinary general meeting, held in Liverpool on December 22nd, a dividend of 5 per cent., making with the dividend of 2½ per cent. paid in June, a total dividend of 7½ per cent., and a further bonus of 2½ per cent., making 10 per cent. for the year.

MIDLAND ELECTRIC CORPORATION FOR POWER DISTRIBUTION.—The debenture transfer books will be closed from the 25th to the 31st inst. inclusive, for the preparation of debenture interest warrants.

ORIENTAL TELEPHONE & ELECTRIC CO.—The register of transfers of 4 per cent. redeemable debenture stock will be closed from December 18th to 31st inst., both days inclusive, for the preparation of warrants for the half-yearly interest due January 1st, 1909.

PUEBLA TRAMWAY LIGHT & POWER CO.—Coupon No. 4, on the five per cent. thirty year first mortgage gold bonds, due January 1st, 1909, will be paid on and after that date at the Bank of Montreal, 47 Threadneedle Street, London.

SOUTH LONDON ELECTRIC SUPPLY CORPORATION.—Subscriptions have been invited during the week by the National Provincial Bank of England, Ltd., on behalf of the South London Electric Supply Corporation to an issue of £100,000 5 per cent. first mortgage debenture stock, having a first charge upon the whole of the company's undertaking. The prospectus states that the company has now about 121 miles of mains laid, and that the capital expenditure to December 31st, 1907, amounted to £300,000.

THE TELEPHONE CO. OF EGYPT.—The register of transfers of 4½ per cent. redeemable debenture stock will be closed from December 18th to 31st inst., both days inclusive, for the preparation of warrants for the half-yearly interest due January 1st, 1909.

COMPANY MORTGAGES

The following are among the mortgages and charges recently filed:—

ADAMS MANUFACTURING CO.—A charge dated November 2nd, 1908, to secure £700 (supplemental to an indenture dated December 19th, 1904), charged on certain hereditaments in Bedford, has been registered. Holders—M. E. Stephens, 11 Mount Street, Berkeley Square, W.; and F. S. Pelissier, 63 Berwick Street, London.

BUENOS AYRES NEW TRAMWAYS CO.—A trust deed, dated October 29th, 1908, to secure £100,000 conversion debenture stock (supplemental to a trust deed, dated December 1st, 1904, securing £500,000), has been registered. Property charged—The company's undertaking and property, present and future, including uncalled capital. Trustees—J. G. le Marchant, 13 Thurloe Square, and J. Head, 40 Lowndes Square, W.

BUENOS AYRES GRAND NATIONAL TRAMWAYS CO.—Trust deed, dated October 29th, 1908, to secure £200,000 conversion debenture stock (supplemental to trust deeds, dated February 16th, 1900, December 9th, 1904, and April 6th, 1906, securing £700,000 similar stock), making a total of £900,000, has been registered. Property charged—A certain concession, lands, property, undertaking, and rights. Trustees—Trustees, Executors and Securities Insurance Corporation, Ltd., Winchester House, E.C.

DAVIS ELECTRICAL CO.—Particulars of £2,000 debentures, created by resolution of October 12th, 1908, have been filed pursuant to section 10 (3) of the Companies Act, 1907, the amount of the present issue being £1,500. Property charged—The company's undertaking and property, present and future, including uncalled capital. No trustees.

COATBRIDGE & AIRDRIE ELECTRIC SUPPLY CO.—A further charge, dated November 26th, 1908, to secure £2,500, charged on the company's undertaking and property, present and future, including uncalled capital and the Coatbridge and Airdrie undertakings, has been registered. Holders, County of London Electric Supply Co., Ltd., Moorgate Street, E.C.

HARPER ELECTRIC PIANO CO.—Issue on November 4th of £500 debentures, part of a series of which particulars have already been filed. (Amount now issued, £1,900.)

Electrical Standardising, Testing and Training Institution. At the recent scholarship examinations, held at Faraday House, Mr. W. B. Cushion of Gresham's School, Holt, Norfolk, was awarded an entrance exhibition of twenty-five guineas a year, tenable for three years.

NEW COMPANIES

BRUCE, PEEBLES & CO.—This company was registered in Edinburgh, on December 5th, with a capital of £250,000 in £1 shares, to acquire the business carried on by Bruce, Peebles & Co., Ltd. (in liquidation), at East Pilton, Edinburgh, and to carry on in the United Kingdom, or elsewhere, the business of electricians, mechanical engineers, suppliers of electricity for the purposes of light, heat, or motive power, brass founders, gas meter manufacturers, tube makers, metal workers, wire-drawers, rope makers, garage, store and warehouse keepers, &c. The subscribers are J. Shields, 141 George Street, Edinburgh; J. Watt, 28 Charlotte Square, Edinburgh; A. Blair, 28 Charlotte Square, Edinburgh; A. W. Watson, 28 Charlotte Square, Edinburgh; W. Blair, 28 Charlotte Square, Edinburgh; D. Porter, 28 Charlotte Square, Edinburgh; J. Gowans, 33 Charlotte Square, Edinburgh. The number of directors is not to be less than three nor more than seven; the first are C. H. McEuen, M. B. Mountain, A. Mackenzie, F. E. Andrews, J. Shields, and A. W. Tait. Qualification, 250 shares. Remuneration, £100 each per annum (chairman £200). Registered office, East Pilton, Edinburgh.

BURMEISTER & WAIN.—Registered in Copenhagen with a capital of Kr.10,000,000 in shares of Kr.2,000 each. Addresses in the United Kingdom, 12 Coleman Street, E.C., and 105 Middle Abbey Street, Dublin.

GRAVITY FLAME ARC LAMPS.—This company was registered on December 17th, with a capital of £5,000 in £1 shares, to acquire from F. Blankensee and others certain patents for inventions relating to Gravity Flame Arc Lamps, and to carry on the business of manufacturers of electric lamps and electrical apparatus, electricians, mechanical engineers, suppliers of electricity, &c. Minimum cash subscription, £100. The number of directors is not to be less than two, nor more than seven; the subscribers are to appoint the first. Remuneration (except managing director), £50 per annum, and 10 per cent. of the net profits available for distribution, divisible. Registered by W. T. Hick, 2 Church Court, Clements Lane, E.C.

LANGWITH PARK ESTATE CO.—This company was registered on December 15th, with a capital of £1,500 in £1 shares, to carry on business as land agents, to plan and erect power stations for the generation of electricity for light or power, to erect plant for the manufacture of coal, acetylene and petrol gas or other luminant for the use of residents of Langwith Park, Collingham, to act as builders, &c., and to acquire and take over the benefit of an agreement for the purchase of the said estate at Collingham, Yorks, made between Mrs. H. E. Reid and W. Walker. Private company. The number of directors is not to be less than three, nor more than seven; the subscribers are to appoint the first. Qualification, £50. Remuneration for first year, one guinea each per meeting attended; afterwards, £75 per annum, divisible. Registered office, North British & Mercantile Buildings, East Parade, Leeds.

OMEGA ELECTRIC LAMP CO.—This company was registered on December 14th, with a capital of £1,000 in £1 shares, to carry on the business of manufacturers of and dealers in incandescent, electric, and other lamps, electric dynamos, motors, accumulators, batteries, cells, apparatus, fittings, and plant, &c. The subscribers are R. E. Haywood, 8 Cottesmore Gardens, Kensington, W., engineer; J. A. Scoular, 23 Normanton Avenue, Wimbledon Park, S.W., electric lamp manufacturer. Private company. The number of directors is not to be less than two, nor more than five; the first are R. E. Haywood and J. A. Scoular. Remuneration as fixed by the company. Registered by Walls, Stallard & Newton, 27 Old Jewry, E.C.

PROVINCIAL ELECTRIC THEATRES.—This company was registered on December 11th, with a capital of £20,000 in £1 shares, to carry on the business of cinematograph and film manufacturers, theatre proprietors, entertainers, cinematograph exhibitors, &c., and to adopt an agreement with R. G. Hill and J. J. Bamberger. Private company. The number of directors is not to be less than 2 nor more than 5: the first are R. G. Hill, F. C. A. Mouillot, S. G. Vernham, and J. J. Bamberger. Qualification, £100. Remuneration, £100 each per annum (chairman £50 extra). Registered office: 20, Bedford Street, W.C.

SALISBURY PUBLICATIONS CO.—This company was registered on December 1st, with a capital of £1,000 in £1 shares, to acquire the paper known as "Biggs & Sons' Contractors' Record and Municipal Engineering," and to carry on the business of publishers, printers, &c. The subscribers are Miss B Biggs, Glebe Lodge, Champion Hill, S.E.; C. H. Biggs, Coombe House, Stanmore Road, Richmond, Surrey, journalist; E. J. Biggs, Glebe Lodge, Champion Hill, S.E., journalist; A. Anson, 18 Eastcombe Avenue, Charlton, Kent, bank clerk; R. W. Weeks, 65 Hayes Road, Bromley, Kent, consulting electrical engineer. Private company. The number of directors is not to be less than two nor more than five; the first are A. Anson and R. W. Weekes. Qualification, 10 shares. Registered office, 139-140 Salisbury Court, Fleet Street, E.C.

TENNESSEE & ALABAMA SYNDICATE.—This company was registered on December 11th, with a capital of £15,000 in £1 shares, to adopt an agreement with J. Weil, and to carry on the business of owners of land, railways, tramways, bridges, iron and coalfields, oil wells, pipe lines, refineries, mines and mining and other rights, railway contractors, machinists, chemical, electrical and mechanical engineers, chemical manufacturers, distillers, druggists, dye-makers, metallurgists, founders, &c. Private company. The number of directors is not to be less than three, nor more than seven; the subscribers are to appoint the first. Qualification, £5. Remuneration (except managing director), 5 per cent. of the distributed profits, divisible. Registered office, 1 Gresham Buildings, Basinghall Street, E.C.

2 INGERSOLL-RAND Belt-Driven Air-Compressors. Capacity 2637 c. ft. free air per minute each machine.

2 ditto, ditto. Capacity 1414 c. ft. free air per minute each machine.

1 Ingersoll-Sergeant Belt-Driven Air-Compressor with automatic unloader. Capacity 285 c. ft. free air per minute.

1 Holman Compressor, Belt-Driven. Capacity 300 c. ft. free air per minute.

Electric Motors for driving above complete with starters, switches and fuses.

1 205-H.P. 400-volts Single-Phase Motor.

2 110-H.P. 400-volts D.C. Motors.

2 14-H.P. Electric Motor Hoists.

All above Machines are in excellent order.

Further details and prices from:—

THE TILBURY CONTRACTING & DREDGING CO., LTD.,
L.C.C. Sewer Works,
Tower Bridge Road, S.E.

THE INSTITUTION OF ELECTRICAL ENGINEERS. The Council is prepared to consider applications for the appointment of Secretary of the Institution from candidates of good standing only, and of not more than 45 years of age. In making the selection, importance will be attached to the following qualifications:—

Administrative experience.
Tact and business capacity.
Acquaintance with the profession.
Knowledge of modern languages.
Technical knowledge.

Applications stating salary required and addressed to "The President of the Institution of Electrical Engineers, 92, Victoria Street, London, S.W.," must be delivered on or before Tuesday, January 12th, 1909.

CABLE JOINTER wanted for Valencia. Must be good worker, under 30, and have thorough knowledge of high tension sleeve jointing. If satisfactory, permanency as foreman. State salary required and past experience to Box A 68, ELECTRICAL ENGINEERING, 203, Temple Chambers, London, E.C.

WANTED, an Engineer having a practical acquaintance with modern electrical developments. Such engineers are in demand, and command large salaries. You can qualify at home, under experts, and by a unique system. Prospectus free, THE BRITISH CORRESPONDENCE SCHOOL OF ELECTRICAL ENGINEERING, Dept. M., 36, Maiden Lane, Strand, London.

John E. Raworth,
Queen Anne's Chambers, 30, Broadway, Westminster, London, S.W.
Chartered Patent Agent.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Dec. 17th, 1908

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

1907 Patents

25,878, **Automatic Transformer Switch.** W. J. DAVY. An automatic switch for breaking the primary circuit of a transformer when the secondary circuit is open, and for closing it when current is required, is the subject of this specification. This switch was fully described in ELECTRICAL ENGINEERING, July 2nd, 1908, page 40. Six claims, six figures.

27,060, **Insulating Material.** J. JOHNSON. This specification describes a hard material suitable for base-blocks for switches and other purposes. It consists of about 40 per cent. sulphur, and 40 per cent. of either lamp black or mica, or a mixture of both. Various earths or colouring matter may be added, or the material may consist solely of the above substances. One claim.

1908 Patents

892, **Double Rotor Induction Motor.** CROMPTON AND CO., LTD., J. C. MACFARLANE, AND H. BURGE. In order to obtain a good starting torque with induction motors, it is necessary to have a high resistance in the rotor at starting, but this must be cut out when the motor is running at full speed, or the efficiency will be low. According to this invention two rotors, one with a high and the other with a low resistance, are mounted on the same shaft, and provision is made to move the low resistance rotor into the stator field automatically as the speed increases. Either a screw thread of fast pitch on the hub and spindle, or an arrangement of weights acting centrifugally can be used for this purpose. Two claims, two figures.

4,657, **High-Resistance Materials.** C. RUZICKA. A resistance composition consisting of 60 parts coal tar, 12 parts quartz, 24 parts potassium felspar, and 10 parts potassium tetraborate, is described in this specification. A moulded rod of this mixture 1 sq. cm. in section and 10 cm. in length, after being heated to a temperature of above 1,000° C., has a resistance of about 10,000 ohms. Instead of coal-tar, resin may be the chief component. In the specification numbered No. 9,762, resistance materials of much lower specific resistance, and suitable for use in heating and cooking apparatus are described. One of these consists of 20 parts iron oxide, 33 parts nickel oxide, 26 parts calcium felspar, and 18 parts bauxite. A material of still lower specific resistance is obtained if iron and nickel nitrites are substituted for the iron and nickel oxides respectively in the above composition. The mixtures are moulded and baked at a high temperature as in the first case. In a further specification, No. 9,763, a resistance material containing carbonised petroleum residue, potassium felspar, and quartz; and another consisting mainly of silicium carbide and potassium felspar, are described. The chief feature in these compositions is the employment of metallic compounds or salts as fluxing or welding agents. In all, nine claims.

5,596, **Self-Starting Mercury Vapour Lamp.** H. A. KENT, H. G. LACELL, AND THE SILICA SYNDICATE. This specification describes a mercury vapour lamp in which the quartz glass containing tube is full of mercury when cold, and has a coil of resistance wire round its centre, which is in series with the mercury in the tube. When the lamp is turned on, the mercury in the centre of the tube is vaporised, and an arc is formed. The pressure of the vapour causes the mercury to flow gradually through narrow necks into chambers provided at either end of the tube, until the arc extends the full length of the tube. When all the mercury has left the tube, the heating coil is automatically short-circuited. The tube is slowly filled with mercury again when the lamp is switched off. Two claims, four figures.

17,414, **Ventilation of Rotors of Turbo-Alternators.** SIEMENS BROS., DYNAMO WORKS, LTD., AND O. KIEFFER. According to this invention, the rotors of turbo-alternators and other electrical machines are ventilated by providing air passages along the tops of the rotor teeth, and drawing air through them. The tops of the passages which are slotted out of the core discs are closed by wedges. Three claims, three figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

1907 Patents

10,560, BROWNE. Electrically-controlled railway block signalling.

19,708, WHITE. Contacts for controllers.

26,048, WINDRATH. Commutating devices.

26,354, RYAN. Electric chain-welding machines.

26,420, BECK FLAME LAMP LTD. (*Deutsche Beck Bogenlampen-Ges.*). Method of extinguishing arc lamps.

26,787, BRITISH INSULATED & HELSBY CABLES, Ltd., & NISBETT. Covering of wires and strips with metal.

26,911, FYNN. Commutating dynamo-electric machines.

27,132, BRITISH THOMSON-HOUSTON CO. (*Allgemeine Elektricitäts-Ges.*). Arc lamps.

27,164, NIX, HARPER, & LANE. Induction apparatus.

1908 Patents

155, RENNERT. Electromagnetic regulating apparatus.

241, WEIGHT. Brakes of automobiles.

1,019, GOLDSTONE, WARD, & GOLDSTONE. Electric cycle lamps.

1,299, EPPENSTEIN. Coincidence telemeters.

1,723, MOORHOUSE & ELLIS. Tramway track brakes.

1,751, STEWART, KILLEN, & HARRIS. Vehicles propelled by electro-mechanical means.

2,985, JUSTICE (*Otis Elevator Co. (Incorporated)*). Electrically-operated ammunition hoist.

4,482, THEMKE. Electrical alarm clocks.

4,550, HILL & MANN. Electric ignition of gas lamps.

5,199, GRAY. Electric cables.

5,415, BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*). Filaments containing zirconium, for incandescent lamps and heaters.

6,644, ECCLES & MAKOWER. Generating electrical oscillations.

6,960, BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*). Alternating-current commutator motors.

7,923, NATHUSIUS, & WESTDEUTSCHE THOMAS-PHOSPHATWERKE-GES. Electric furnaces.

8,018, MEYERLING. Ampere-hour meters.

8,255, DICKINSON. Tramway brake.

10,041, SCHNEEWEIS. Dry cell with ventilating channels.

10,171, SIEMENS BROS. & CO. (*Siemens & Halske Akt.-Ges.*). Means for reducing the reflex action at the points of connection of electrical conductors.

10,317, MERSHON. Insulating supports for high-tension conductors.

10,632, PATERSON & DARK. Clamping device for electric contacts or brushes.

12,411, MOZINGO. Electric mail railway system.

12,468, SAHULKA. Wireless telegraphy.

12,834, STENTON. Signalling apparatus.

13,095, KEARNEY. Tube railway system.

15,273, HEDIN. Apparatus for indicating temperature.

16,849, HALL. Safety devices for ignition systems.

17,410, LUNDBERG, LUNDBERG, & LUNDBERG. Switches.

17,417, SIEMENS BROS. DYNAMO WORKS, Ltd. (*Siemens Schuckertwerke-Ges.*). Commutators.

17,772, MACKENZIE (*Telephon Disinfectoren-Ges.*). Apparatus to disinfect telephone mouthpieces.

17,841, PAGE (*Telegraph Transmitting Instrument Co.*). Keyboard telegraphic transmitters.

18,579, RATEAU. System of governing low-pressure turbines driving generators coupled in parallel.

18,713, S.P. (SUCHOSTAWER PATENTS) SYNDICATE LTD., & SAYERS. Electric traction on the surface contact system.

19,388, EBNER. Interruptor for electric ignition.

20,179, SERAGNOLI. Electro-pneumatic device to indicate attempts to tamper with articles to be protected.

20,352, HANKIN & WOLFF. Resistances for electric circuits.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

1908 Patents

10,885, WOLFRAM-LAMPEN AKT.-GES. Manufacture of metal filaments.

10,889, CHAUDET. Carbon holders for arc lamps.

25,535, BLAGBURN. Process of obtaining nitrogen from the air.

25,537, ALLMANNA SVENSKA ELECTRISKA AKTIE-BOLAGET. Starting and regulating compensated repulsion motors.

26,053, EGNÉR & FREDRIKSSON. Aerial electric cables.

Applications for Amendment

Further particulars and instructions as to procedure in opposition to amendment will be found in the Official Journal of the Patent Office of Dec. 16th, 1908.

22,031, of 1902. **Mariners' Compass.** The Executors of the late LORD KELVIN, F. W. CLARK, and KELVIN & JAMES WHITE, LTD., seek leave to revise the wording of the second claim in this specification.

24,950, of 1906. **Arc Lamp.** H. MOSEY seeks leave to amend this specification, which relates to a gravity-fed arc lamp with converging carbons. The amendment consists in substituting five new claims for the existing ones, to limit the scope of the invention.

All letters to be addressed to "Electrical Engineering," at the EDITORIAL AND PUBLISHING OFFICES: 203-206, TEMPLE CHAMBERS, LONDON, E.C.

Telegrams: "Circling, London." Telephone No.: 5509 Holborn.

Cheques to be made payable to THE KILOWATT PUBLISHING CO., LTD., and to be crossed LONDON AND WESTMINSTER BANK (Temple Bar Branch).

BINDING "ELECTRICAL ENGINEERING."—Vol. IV. of "Electrical Engineering" (July December, 1908) closes with this issue. An index for the volume will be ready on Thursday next, Jan. 7th, and copies may be ordered from any newsagent or bookseller at the price of 1d. each; or they will be sent post free from THE KILOWATT PUBLISHING CO., Ltd., 203-206, Temple Chambers Temple Avenue, London, E.C., for 1½d. Binding Cases, including index, will be ready on the same date, price 2s. each, post free 2s 4d. Readers can have their volumes bound by their own bookseller; or they may send their numbers to us, carriage paid (with the reader's name and address), and a remittance of 4s 6d. under separate cover. The volumes will then be bound and returned carriage paid to any address in the United Kingdom, or carriage forward to the Colonies or abroad.

"Electrical Engineering," although the Cheapest Electrical Paper (Price 1d. weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

THE report of the Departmental Committee on "Fair Wages" Clauses in Government Contracts shows that there are no widespread defects in connection with the enforcement of such clauses. The Committee express the opinion that the resolution passed by the House of Commons on this question in 1891 was not intended to set up new standards of wages, and they therefore cannot see their way to alter the wording of existing clauses in Government contracts. The recommendations of the Committee take the form of suggestions for preventing evasion of "fair wages" clauses, and for giving facilities to trades unions to ascertain the names of firms carrying out Government contracts. (Page 830.)

THE Parliamentary session of 1908 is reviewed from the point of view of electrical legislation in a special article. Apart from the London electric power question, which has at last been placed upon a footing satisfactory to all parties, there is little of special moment to refer to, the session in other respects being quite uneventful. (Page 831.)

ELECTRICAL driving has been adopted in the carpet factory of Messrs. H. Mackay & Co., at Durham. Continuous-current 480-volt motors are used, varying up to 20 b.h.p. in size, and power is taken from the County of Durham Electrical Power Distribution Co. The steadiness of speed obtained results in much more satisfactory operation of the large looms, and a great saving of time in tying broken threads and repairs to looms. (Page 832.)

AN article by Mr. A. G. Ellis deals with the relative weights and costs of alternating and continuous-current generators, and particularly the influence, on these quantities, of the rated speed and the rated output. The curves given are based on designs for a large number of machines, many of which were carried out by the author under the direction of Mr. H. M. Hobart. The conclusions are that high speeds are distinctly more suitable for A.C. generators than for C.C. generators, both as regards operation and manufacturing cost. In both cases there is, for each rated output, a

Digitized by Google

certain speed at which the weight and cost reach minimum values. (Page 833.)

A FURTHER letter from Mr. Hugo Herzfeld relating to the German electrical industry is given in our correspondence column. Dr. H. Borns writes to explain further his remarks in the discussion of Messrs. Cramp and Hoyle's Paper on the production of nitric acid by electric discharges. (Page 835.)

ONE of the tendencies in the design of heavy electric locomotives for high speeds, as evidenced by recent developments in America, appears to be a return to the use of radial pony and swivelling bogie trucks, with the consequent sacrifice of adhesion weight in order to obtain better riding qualities. The New York, New Haven, and Hartford Railway is remodelling all its locomotives by adding a pony axle in front of the driving wheels of each motor truck, and the new locomotives of the New York Central Railway have swivelling bogie trucks at each end. (Page 836.)

THE following books are reviewed in this issue:—"An Elementary Manual of Radiotelegraphy and Radiotelephony for Students and Operators," by Dr. J. A. Fleming; "Elementary Dynamo Design," by W. B. Hird; "Elementary Manual on Steam and the Steam Engine," by Andrew Jamieson; "The Elementary Theory of Direct-Current Dynamo Electric Machinery," by C. E. Ashford and E. W. E. Kempson; "The Management of Dynamos," by G. W. Lummis-Paterson; "The Deinhardt-Schlomann Series of Technical Dictionaries in Six Languages; Vol. IV."; and "Field Telephones for Army Use," by Lieut. E. J. Stevens. (Page 838.)

A PAPER by Mr. F. H. Corson was read last week before the Institution of Civil Engineers, describing a series of tests undertaken at the Blackburn Corporation Electricity Works which indicated an average consumption of 5·15 lbs. of coal and an evaporation of 33·9 lbs. of water per kw.-hour. (Page 838.)

AN article by a correspondent investigates the cost of heating by electrical means for such metallurgical processes as the electric furnace is suitable, and points out that owing to the much more efficient way the heat is applied, the actual costs of direct heating by fuel and electrical heating are not so different as might be imagined. (Page 839.)

A SPECIAL committee of an American Electric Railway Association has prepared a report on the use of carbon brushes with traction motors. In this report the various types of brushes are classified, and tests are described which were devised for the purpose of determining the relative strength and durability of different brushes and the current-carrying capacity. (Page 840.)

A PAPER on the utilisation of exhaust steam in low-pressure turbines was read by Mr. R. F. Halliwell last week before the Rugby Engineering Society. The author, after dealing with the historical and theoretical aspects of the subject, described various forms of the Rateau and other heat accumulators, and gave details of some important exhaust steam turbine installations. (Page 841.)

THE early experimental wireless telegraph installation at the Eiffel Tower, the temporary plant with which messages were sent to Casa Blanca, and the powerful permanent equipment now under construction are described in an illustrated article. (Page 843.)

UNDER "Electrochemistry and Electrometallurgy" we notice a new process for obtaining a brilliant deposit of zinc, which, if shown in practice to be really satisfactory, should lead to an increase in the adoption of electro-zincing. The electric steel furnace is recommended to refine steels required for rails and ordnance, as steel so refined is much less apt to develop faults. (Page 844.)

A RECENT article in a French contemporary contains an analysis of a number of replies which have been received from users of steam turbo-generators on the Continent, and contains a good deal of interesting information on the subject. (Page 845.)

AMONG the specifications published by the Patent Office on Thursday last is one by the British Thomson-Houston Co., Ltd., relating to a means of removing the slag from the tips of flame carbons. A patent taken out by W. N. Stewart, E. B. Killen, and F. Harris relates to a petrol-electric power-transmission system for vehicles in which the transmission is always electrical. A dyna-motor with rotating field-system is used, the field-system being coupled to the engine. H. Gray has a specification describing a method of stranding cables to avoid the longitudinal movements with variations in temperature, and a specification by the British Thomson-Houston Co., Ltd., relates to the manufacture of filaments of pure zirconium for electric lamps. A method of improving the commutation of repulsion motors at high speeds has also been patented by the British Thomson-Houston Co., Ltd. Designs for two-way tumbler and press-button switches are described in a specification by A. P. Lundberg, and Siemens Brothers' Dynamo Works, Ltd., have one for a method of cooling commutators. Short abstracts of the above are given in our Patent Record. Among the patents expiring during the current week is one by O. B. Shallenberger for an induction meter, and another granted to J. B. Barton for an enclosed arc lamp. This latter, though communicated by W. Jandus, is not the Jandus master patent. (Page 847.)

THE Victorian Railway Commissioners have considered Mr. Merz's report on the proposed electrification of the Melbourne suburban railway system, but while agreeing with the technical details as to system suitable, they do not concur as to the financial estimates, and do not consider that the large capital expenditure would be justified. They recommend, therefore, that the proposed electrification be not taken in hand at present. (Page 848.)

OWING to the increase of the fares upon certain tramway routes in Colchester, the public are refusing to patronise these lines.—The Devonport & District Tramways Co. have notified the Corporation of their intention to cease running their cars over certain leased lines after January 16th.—During the course of the construction of the pump chamber at the new electricity works at Dundee, the foundations gave way, and the whole of the concrete structure sank a depth of about four feet.—A Board of Trade inquiry has been held into an application by the Farnham & District Electric Supply Co. for permission to erect overhead wires.—The dispute between the Stepney Borough Council and the City of London Electric Lighting Co. as to the lighting of the Tower of London, has been put an end to by the Tower authorities deciding to take their supply from the Borough Council.—The promoters of the proposed tube railway under the River Tyne have suggested that the North and South Shields Corporation should contribute half the necessary capital, namely, £100,000.—The Plymouth Gas, Light, & Coke Co. has invited the Corporation to take part in a public competition for the purpose of demonstrating the relative advantages of gas and electricity for public lighting. (Page 848.)

THE Grimsby Corporation require continuous-current motors and starting panels, and the Oldham Corporation feeder cables, pillars, ducts, &c.—A Local Government Board inquiry has been held at Dover (£5,000).—Tenders are invited with regard to the supply of electricity at the Brussels Exhibition in 1910.—A tender has been placed for the construction of the Watford station of the new Euston-Watford electric railway. (Page 850.)

The year which closes to-day will be distinguished in the annals of electrical engineering chiefly as the year during which the metal filament lamp came into general use. Besides the furthering of manufacturing facilities which has enabled several of the existing patterns to be put on the market in quantities, a good deal has been done in extending the range of usefulness of the lamps, both for higher voltages and smaller candle powers. Not the least important of the developments, however, has been the opening up of the possibilities of great reductions in the cost of country-house lighting by the extended use of the 25-volt high-efficiency lamp. There has been a good deal of discussion as to the effect of the new lamps on the electric supply industry; but while the immediate effect is to decrease the amount of electrical energy sold for a given capital expenditure, and particularly to attract the smaller consumers, the cost of whose services are disproportionate to the revenue they bring, there can be no doubt that the improvement in the efficiency of illumination available is a distinct step forward in the competition with gas, and cannot fail to lead to ultimate benefit to the supply authority. Progress has, of course, been achieved in other branches of electrical engineering, notably in the design of motor starting and control apparatus in which the Manchester Exhibition, in itself an important feature of the year, was particularly rich. In no other direction, however, have such large strides forward been taken than in connection with the metal filament lamp. Notwithstanding the refreshing remarks of optimists, the British electrical industry has had much to struggle with during the past twelve months, but signs have not been wanting that the coming year may see the commencement of the long-wished-for revival. The year will be to some extent memorable also from the point of view of legislation affecting electrical engineering, both by reason of the clause of the new Patent Act which provides for the revocation of foreign patents not worked in this country coming into force, and on account of a definite conclusion having been finally arrived at as regards the power supply of London. Speaking of the heavier branches of electrical engineering, the marked advances have been rather in the realm of lighting than power or traction, for, while there has been steady progress in both of the latter, no new schemes of any great importance have seen their inception. Single-phase traction has been put into practice experimentally on the Midland Railway, but the general problem of electrification of main line railways cannot be regarded, in this country, at any rate, as being nearer to its solution. Wireless telegraphy may be said to have reached a steadier state, and wireless telephony has progressed far towards emerging from the experimental stage. In the New Year, which we hope will be a prosperous one to all our readers, we may anticipate a continuance of the metal filament lamp "boom," and that a fresh impetus will be given to the applications of electric power, especially in collieries.

The "Fair Wages" Clause in public contracts has always been a favourite topic for discussion and argument by the labour leaders, and some of the more ardent spirits, had they been allowed, would have violated all commercial principles by the insertion in such contracts of words so stringent in character as to render the cost of goods purchased on behalf of the public, out of proportion to their real value. As far back as 1891 a resolution was passed in the House of Commons to the effect that provision should be made in all Government contracts for securing the payment of a fair rate of wages for all work carried out in connection with these contracts, and since then words to this effect have been inserted in all contracts entered into by the various Government Departments. Soon after the present Government took office, however, representations were made that by reason of the defective wording of the resolution of 1891, evasion of its terms was a simple matter, and was more or less practised. The result was that the Treasury, in August, 1907, appointed a Committee to investigate the whole question, and to report whether any administrative changes were necessary in order to enable the objects of the resolution to be attained more effectually. The report of this Committee, which is summarised on another page, shows that since the passing of the resolution of 1891, no widespread defects in the working of the "Fair Wages" Clauses in Government contracts have manifested themselves, and that on the whole there has been no appreciable cause for complaint in this direction. The Committee emphatically reject the proposal of the trades unions to insert ambiguous words in the clause to the effect that the trade union rate of wages shall be paid, and that trade union conditions must be observed. These altogether ignore the varying social and other conditions of different districts, in order to gain advantage of which many firms have moved their works from the large towns to less congested parts. If the apparent ideal of the trades unions to have a uniform rate of wage over the whole of the country is to be granted, then one of the inducements for firms to erect their factories in more congenial surroundings is taken away, with a consequent deprivation of the men of the domestic advantages attached to such conditions of labour. It is well, therefore, that the Committee prefer the present wording of the clause, which provides for the payment of the union rate of wage in the particular district in which the goods are manufactured. For the rest, the Committee make certain recommendations to arrive at further uniformity in the wording of the clauses adopted by the various Government Departments, and generally for the payment of the standard rates in special circumstances. Having in mind the pressure which is often brought to bear upon local authorities in this matter, we trust that they, on their part, will resist any attempt to force upon their contractors clauses which are too stringent to be adopted by Government Departments.

According to the *Times*, the Bureau of Manufacturers at Washington has received the following report from Mr. J. N. McCunn, the United States Consul at Glasgow:—

"With regard to the clause in the Patents Act 'to an adequate extent,' I am informed that it would appear to be perfectly in order, in the meantime, to manufacture the parts of a machine in the United States and have them assembled in the United Kingdom. The ground on which this view is taken is that each part of the machine, taken separately, is not a patented article, the patent merely applying to the machine as a whole. No test case has yet been taken in the British Courts, and I am informed that the above is the generally accepted reading of the law until such a test case is brought."

Digitized by Google

We cannot say that we agree with Mr. McCunn's argument, nor will we accept his statement that this reading of the revocation clause is generally accepted. It is, in fact, a point on which it is almost impossible to generalise, and each case must obviously be considered on its merits. The Act is very clear that revocation of patents may be applied for on the ground that "the patented article or process is manufactured or carried on exclusively or mainly outside the United Kingdom," and that before he can refuse to revoke a patent, the Comptroller must be satisfied that "the patented article or process is manufactured or carried on to an adequate extent in the United Kingdom," or must accept satisfactory reasons for this not having been done. The words "to an adequate extent" obviously apply to the number of articles manufactured, and not to the method of manufacture. As an example of the different constructions that might be placed on the clause in question, we may take two cases. Let us suppose that a patent has been taken out for a method of ventilating the rotors of alternators and motors; if the rotor and all the other parts of the machine were sent over ready manufactured from America, and were merely assembled here, we cannot think that it could be claimed that the patented article was manufactured here simply because the patent was for an alternator or motor with such a rotor. On the other hand, it is clear that in the case of a patent process for making filaments of incandescent lamps, nothing would prevent the maker from buying the globes and caps abroad so long as he manufactured the filaments and lamps here, and if the only new patent about the lamp was the method of suspending the filament, he could obviously buy the filament abroad as well. Doubtless, however, there will be some cases during the next few years which will make the law on this matter a little clearer, but in the meantime, we recommend our friends across the Atlantic to think twice before they follow implicitly the advice of their Consul in Glasgow.

"FAIR WAGES" CLAUSES IN GOVERNMENT CONTRACTS

ON February 13th, 1891, the House of Commons passed the following resolution, which has since come to be known as the "fair wages" resolution:—"That in the opinion of this House, it is the duty of the Government in all Government contracts to make provision against the evils recently disclosed before the Sweating Committee, to insert such conditions as may prevent the abuse arising from sub-letting, and to make every effort to secure the payment of such wages as are generally accepted as current in each trade for competent workmen." This resolution aims at (1) the prevention of the evils disclosed before the Sweating Committee; (2) the prevention of abuse arising from sub-letting; and (3) the payment of current rates of wages.

On August 14th, 1907, the First Lord of the Treasury recommended that a Departmental Committee should be appointed to consider the working of this "fair wages" resolution as embodied in Government contracts, and to report whether any administrative changes, especially with a view to the prevention of evasion, the enforcement of the rate current in the district, and greater uniformity of interpretation and working, was desirable in order to enable the objects of the resolution to be more effectually attained. In pursuance of this recommendation the following Committee was appointed:—

Sir G. H. Murray, K.C.B., Secretary to the Treasury, Chairman.

Mr. H. De La Bere, C.B., Assistant Director of Army Finance, War Office.

Mr. A. Wilson Fox, C.B., Comptroller-General, Commercial, Labour and Statistical Department of the Board of Trade.

Mr. A. F. King, Second Secretary, General Post Office.

Mr. F. W. Black, Director of Contracts, Admiralty.

Mr. R. Bailey, M.V.O., Controller of H.M. Stationery Office; and

Mr. J. B. Westcott, M.V.O., H.M. Office of Works.

Mr. J. J. Wills, of the Board of Trade, Secretary.

On the death of Mr. Westcott, Mr. J. H. Hillier, Controller of Supplies, H.M. Office of Works, was appointed a member of the Committee in January, 1908.

This Committee has now reported the result of their deliberations. Evidence was taken from 68 witnesses, of whom 41 represented trade unions and 22 employers' organisations. In addition, evidence was submitted by four ladies on the question of women's work, and by the Clerk to the London County Council on the working of the "Fair Wages" clauses in the Council's contracts. The Committee also received communications from the Employers' Parliamentary Council, the Parliamentary Committee of the Irish Trade Unions Congress, the London Chamber of Commerce, and the Town Clerks of Bradford, Glasgow, Leicester, Liverpool, Sheffield, and West Ham.

The Committee, in their interpretation of the resolution, point out that in their view it was not intended to set up new standards of wages, but to secure that the wages paid for Government work were those ordinarily paid by good employers to competent workmen in each trade in the district where the work was carried out, and to prevent Government contracts from falling into the hands of employers who were able to quote lower prices by undercutting their competitors in the rates of wages paid. It is also pointed out that the resolution does not contain the word "district," but that the phrase "wages current in each trade for competent workmen" is, in practice (and the Committee think rightly) interpreted as wages current in the district in which the work is carried out. This principle, it is pointed out, is already given effect to in various ways in all Government and other public contracts, and the conclusions arrived at by the Committee are summarised as follows:—

(*a*) We recommend that the present wording of the Fair Wages Clause, which obliges the contractor to pay the current rates of wages for competent workmen in the district where the work is carried out, should be retained.

(*b*) While we do not recommend that words intended to enforce the observance of "Trade Union conditions" should be inserted in Government contracts, we think that such conditions of employment as are generally accepted in the district in the trade concerned must be taken into account when considering the question whether a particular contractor is observing the Fair Wages Clauses.

(*c*) We think that where persons are employed at piece rates of wages on work for which a current time rate exists, the general principle that the piece work earnings for a given period should exceed the standard time wages for the same period on similar work should be recognised; and we recommend that contractors should be enjoined to keep proper records of the time worked by their workpeople in all cases of this kind.

(*d*) In the case of trades which can be identified as unorganised, or in any other cases in which the Department concerned considers that difficulties are likely to arise in ascertaining the "current rates of wages," the following recommendations are made:—

(1) That the Government should fix in the contract the rates of wages to be paid to the various classes of workpeople engaged for the various operations involved in the work.

(2) That a minimum time rate of wages should be fixed, below which no person engaged on the work under the contract shall be paid.

(3) That wages in trades such as those in question should be dealt with by Wages Boards.

(4) That the contractor should be required, when tendering, to furnish a schedule of the rates of wages and hours of labour which he proposes to pay and observe in the execution of the contract.

(*e*) We cannot recommend that Government contracts should be restricted to what are known technically as "fair houses," but we think that great care should continue to be taken in selecting firms to be placed on the list of contractors, so as to ensure that only good employers shall be admitted.

(*g*) We recommend that, so far as practicable and at the discretion of the Departments concerned, the names and addresses of all firms obtaining Government contracts should be published in the "Board of Trade Journal" or "Board of Trade Labour Gazette."

(*f*) We recommend that in all works where Government contracts are being executed a copy of all the labour conditions of the contracts should be prominently exhibited for the information of the workpeople.

(*h*) We recommend that there should be uniformity among the Departments in the wording of all clauses dealing with the conditions of labour in contracts affecting the same trades.

(*i*) We think that every effort should be made to ensure all possible co-operation among the different contracting Departments in such matters as inspection, the investigation of complaints, and the interpretation of the Fair Wages Clauses in difficult cases. With a view to furthering this object we suggest that a Committee should be formed of representatives of the different Contracting Departments, who should meet from time to time for the discussion of matters of common interest, and the settlement of disputed questions.

ELECTRICAL LEGISLATION IN 1908

MEMBERS of the electrical manufacturing industry, looking back upon the Parliamentary session just closed, will be disappointed if they expect to find in the measures that have been passed any promise of direct benefit. The schemes that have been successful will not call for any large supplies of machinery and plant for their fulfilment, and the promoters of a number of hopeful proposals were forced to withdraw them through the insistence of local authorities upon exercising to the full the rights and powers which Parliament conferred upon them in almost prehistoric times. This more especially applies to tramway undertakings, and although we are supposed to regard the present as a progressive age, the absence of the application of this spirit to the general electrical legislation of the country is one of the most striking features of our governmental ideas. The evil effect of such a condition of affairs upon the expansion of the industry has been urged upon successive Governments for the past ten years without effect, and the diminishing number of electrical Bills with succeeding years is undoubtedly traceable in a large degree to the need for modernising the laws under which electrical enterprises are conducted. When this happy day arrives British capitalists will no doubt be more ready to embark upon schemes at home instead of investing their money in colonial and foreign undertakings which at present offer a greater guarantee of security for their investments.

For the fourth successive year the feature of the past Parliamentary session has been the London Electric Power Bills, but the facts are too fresh in our minds to need recapitulation. The rejection of the "bulk" supply scheme, followed by permission to the existing companies to co-operate to any extent they please—the *quid pro quo* being the substitution of the London County Council for the borough councils, as the purchasing authority—has had the effect of restoring to the companies their prestige of five years ago, and their financial outlook is considerably brighter. The companies may now put their domestic affairs into order, and the linking up of the various electrical undertakings, both company and municipal, may be looked to as the first item on the programme. Already movements in this direction have been made, and it is conceivable that the inherent municipal prejudice to company working will be broken down when it is realised that advantages are more likely to accrue from co-operation than opposition. Two other Bills relating to power supply were dealt with, viz., the South Wales Electrical Power Distribution Co.'s Bill and the Dublin and Central Ireland (afterwards changed to the Central Ireland) Electric Power Bill. A somewhat melancholy interest attaches to the former, inasmuch as it provided for the disintegration of the company's undertaking in South Wales and the disposal of the various power houses, either to the respective local authorities or to local companies, a method of reconstruction which fortunately shows every prospect of putting the company upon a sound financial footing. From the sentimental point of view, of course, the position of the company, having, as it does, a field of operations second, probably, only to the Newcastle district, is to be regretted. The proceedings in connection with the Irish electric power scheme typify the wisdom of numbering a member of Parliament amongst one's friends, for by the good offices of Mr. John O'Connor the promoters of the scheme went through the most uncommon experience of having their Bill referred back to the Committee after it had been rejected "on its merits." In the meantime, they had eliminated what were rightly assumed to be the objectionable features, and succeeded in getting it passed at the second attempt, an opportunity for revision which would be much appreciated by many promoters, but which falls to the lot of exceedingly few. On the engineering side this scheme is interesting on account of the intention to utilise peat to generate gas for the engines which will drive the generators, and it remains to be seen whether the hopes entertained of turning the bogland to the south of Dublin into a second Niagara, from the industrial point of view, will be realised.

A certain amount of legislation has been put upon the Statute Book in relation to the London electric railways, but with the exception of the North-East London Railway Bill, which was for an extension of time for the construction of the line and for the raising of capital, it related to financial adjustments on the part of affiliated companies of the Underground Electric Railways Company of London, viz., the District Railway Co. and the Great Northern, Piccadilly, & Brompton Railway Co.

Quite a number of tramway Bills were promoted, but the only contested one which was passed was that of the London United Tramways, Ltd., for constructing a line over King Edward VII. Bridge at Kew. The remainder were either unopposed or had to be withdrawn. Included in the latter were the London and Windsor Tramroads and Tramways Bill, the West London, Barnes, and Richmond Tramways Bill, and the Croydon and Southern District Tramways Bill. The Belfast Tramways Bill which sought to purchase the undertaking of the Cavehill and Whitewell Tramways Co. at a price of £60,000—in order to prevent the company coming to Parliament to secure reciprocal and compulsory running powers over the lines of the Corporation—was rejected on the second reading debate, a very pronounced opposition to the proposal having been displayed by an influential section of the ratepayers. The tramway Bill of the London County Council did not contain very extensive or important powers, for the reason that authority for constructing tramways over the main routes or for converting important existing lines has already been obtained, leaving little else than small linking up lines to be promoted in the future. The London County Council, however, is proceeding with a number of lines for which it possessed powers previously, so that there will be a certain amount doing in the tramway industry for some time to come. The following provincial corporations and companies were granted, in omnibus Bills, additional tramways, but in no case did the proposed capital expenditure reach considerable proportions:—Liverpool, Blackburn, Rochdale, Wolverhampton, Doncaster, Bristol Tramways Co., and the Nottinghamshire & Derbyshire Tramways Co. The Macclesfield & District Tramways Co. was permitted to abandon the powers granted a few years ago for the construction of tramways, the company having meanwhile disposed of its electric lighting order to the Macclesfield Electric Light & Power Co. The Tramway Company will be wound up.

We give below a list of the Bills promoted, together with the Provisional Orders for tramways and lighting granted by the Board of Trade, and subsequently confirmed by Parliament.

ELECTRIC LIGHTING PROVISIONAL ORDERS CONFIRMED.

Electric Lighting Provisional Order Confirmation Bills, Nos. 1 *and* 2.—Bispham-with-Norbreck, Caldy Manor, Carmarthen, Fleetwood, Halesowen, Heswall, Lowestoft (Amendment), and Woking (Extension); Barrhead, Clydebank (Amendment), Dundee (Extension), and Rutherglen (Amentment).

Electric Lighting Provisional Order Confirmation Bill, No. 3.—Bridgend (Extension), Hendon (Amendment), Llandaff and Dinas Powis (Amendment), Llansamlet, Oulton Broad, Sowerby Bridge (Amendment), and Tewkesbury.

TRAMWAY PROVISIONAL ORDERS CONFIRMED.

Tramway Provisional Order Confirmation Bill No. 1.—Manchester Corporation.

Tramway Provisional Order Confirmation Bill No. 2.—Potteries Electric Traction Co., Liverpool Corporation.

AN ELECTRICALLY OPERATED CARPET FACTORY

AN example of an old-established manufacturing works which has recently availed itself of the advantages to be obtained by electric driving is to be found in the electrically equipped carpet factory of Messrs. Hugh Mackay & Co., at Durham. Originally started in 1816 under the style of Henderson & Co. to make "Scotch" and "Brussels" carpets and similar goods, with a plant including steam boilers and engines and a complexity of shafting, the firm five years ago changed its name and incidentally its motive power, and a gas engine was installed, which has more recently been superseded by electric driving.

Before describing the electrical equipment of the works, it may be interesting to mention briefly the process of carpet making as practised by this firm. The wool yarn which is to be made into the rug or carpet is received in an oily state, and has first to be thoroughly washed and "scoured." It then proceeds to the dyeing vats, and is afterwards stored in long hanks or skeins in racks. In the same room there are also stored cotton and linen threads for warp threads and binding wefts respectively. The first step in the handling of the yarn is to place it on a winding machine, which forms the yarn into tightly wound "cops" ready for the shuttle of the loom. The warp of the carpet, whether of worsted, cotton, or linen, is first wound by a "reeling off" machine from the skein on to bobbins, which are then run off through a series of combs on to a slowly rotating warping machine, or large cylinder formed of a series of parallel slats. From this the thread is re-wound in a series of parallel coils on the "beam" or yarn carrier, which goes at the back of the loom and holds the various warps of the carpet.

Some of the carpets being produced at the time of our visit were four-ply, necessitating the arrangement of four wefts vertically above one another at one weaving. In pile carpets, the "pile" or height of the carpet is formed by the wool or worsted passing from frames (directly behind the loom) over a series of wires, held up edgeways. These carry a small knife at the end, which, on being drawn out, severs the wool, and causes the ends to stand up to form a "cut pile." In order to trim these evenly the carpet on leaving the loom is passed through a rapidly revolving shear, which crops the carpet to a fine, even thickness.

Electrical power for the driving of all these machines is obtained from the 480-volt direct-current supply of the County of Durham Electrical Power Distribution Co., Ltd., whose Silver Street sub-station is close to the factory. The whole of the installation is carried out on a surface wiring system, insulated leads held in porcelain clips being used. The original Campbell gas engine of 35 h.p., which, with its cooling tanks, &c., took up a space of about 27 ft. by 18 ft., has been replaced by three motor drives operated by a 17 h.p., 20 h.p., and 8 h.p. Holmes motor respectively, furnished with Reyrolle drum starters. The first drive operates the reeling-off machine, shearing machine, several small looms, and some Wilton looms, together with the stamping machines for the cards. The second drive gives power to a number of large looms and the cop winders, &c. The third motor, which is of a specially low speed, operates the warping mill, and some repair shop tools, such as a lathe, drilling machine, grinder, &c. The reason for the slow speed is that owing to the extremely low rate of revolution of the warping mill the shaft driving it has to run as low as 80 r.p.m. The splitting up of the drive into three sections did away with a considerable amount of cross shafting and bevel gear, which seriously reduced the working economy of the factory.

It may be interesting to note one of the main reasons for adopting electrical drive in this factory. Apart altogether from considerations of economy and space, it was found that the variation of speed of the gas engine produced an erratic action of the hammers which drive the shuttles across the loom. Some of these looms are up to four yards wide, and when the speed failed slightly the shuttle would not travel the full length of the weft. If, however, the speed rose excessively it occasionally happened that the shuttle was driven with such violence that the loom was broken. The adoption of electrical drive produced steady and smooth action, involving a great saving of time in tying broken threads and repairs to looms.

Electric Smelting of Iron.—It will be remembered that two years ago some tests on the electric smelting of iron were carried out at Sault Ste. Marie by Dr. Eugene Häänel. According to *Canada*, a large firm of Swedish iron-smelters, who have since been making extensive experiments, with successful results, are about to make a further trial with a larger furnace consuming some 800 h.p., and have invited Dr. Häänel to be present at the trials. It is said that if the process is carried out on a sufficiently large scale, the cost of producing iron in this way would justify its use in Canada, in some of the districts where energy is supplied at cheap rates.

Manufacture of Nitrates by Electricity.—The British Vice-Consul at Zurich reports that a large firm in Switzerland propose to apply some of their available electric power to the manufacture of nitric acid and saltpetre from atmospheric nitrogen. The firm have recently concluded an agreement with the proprietors of a new patent, by which the patent rights in Switzerland and Austria-Hungary become their property. Extensive works are being built at Chippis, in the canton of Valais, for the manufacture of nitric acid and nitrates, and it is hoped to commence working in the course of the year 1909.

Faraday House Journal.—The January issue of the Faraday House Journal, which has just made its appearance, contains a quantity of items of personal news regarding a large number of electrical engineers who are old students of the Electrical Standardising, Testing and Training Institution, and includes excellent portraits of Mr. C. D. Taite, chief engineer of the Lancashire Electric Power Co., and his wife. The technical articles and notes include an illustrated description of one or two of the stands at the recent Manchester Exhibition.

COMPARATIVE WEIGHTS AND COSTS OF ALTERNATING- AND CONTINUOUS-CURRENT GENERATORS

By A. G. Ellis

THE investigations described in this article have been carried out chiefly with a view to obtaining more precise information as to the relative weights and costs of alternating- and continuous-current generators, and also as to the influence on these quantities of rated output and speed on the design of C.C. and A.C. generators.

The curves in Figs. 1 and 2 relating to C.C. machines apply to designs for rated outputs not exceeding 1,000 kw., whereas the A.C. curves in Figs. 3 and 4 extend

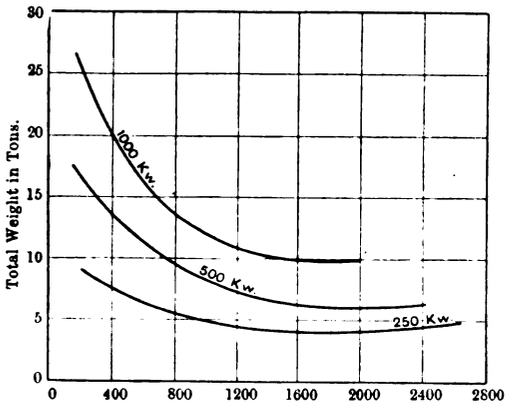

Fig. 1.

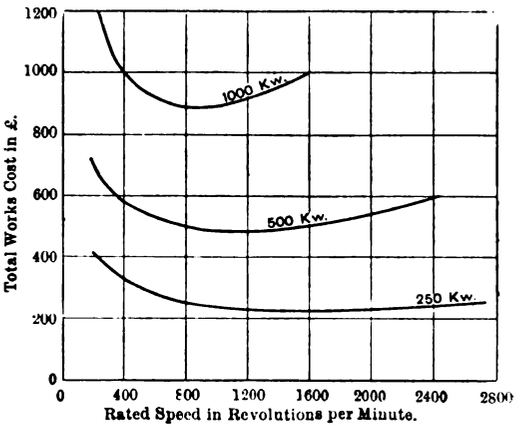

Fig. 2.

Figs. 1 and 2.—Curves for Total Weight and Total Works Cost of Continuous-current Generators.

two of the most important factors in dynamo machine problems, namely, the rated speed and the rated output. The data on which the deductions are based are plotted in Figs. 1 to 4. Figs. 1 and 2 showed respectively the Total Net Weight and the Total Works Cost* for continuous-current generators of 250, 500, and 1,000 kw. rated output, for rated speeds ranging from 200 r.p.m. to 2,800 r.p.m. Similar curves for alternating-current polyphase designs are shown in Figs. 3 and 4 for the same range of rated speeds, but for rated outputs of 375, 750, 1,500, 3,000, and 6,000 k.v.a. These curves are based on designs for a large number of A.C. and C.C. generators, many of which were carried out by the author under Mr. Hobart's direction. Many of these designs were made for the express purpose of arriving at more definite conclusions regarding the effect of the rated output and speed on the design of C.C. and A.C. generators.

* The expression "Total Works Cost," as employed in this article, designates the total manufacturing cost of the machine, as delivered to the stores, *i.e.*, including the material and labour costs of the machine, and the establishment charges. The expression "Total Weight" designates the total net weight of the machine as completed, including the shaft and outboard bearing.

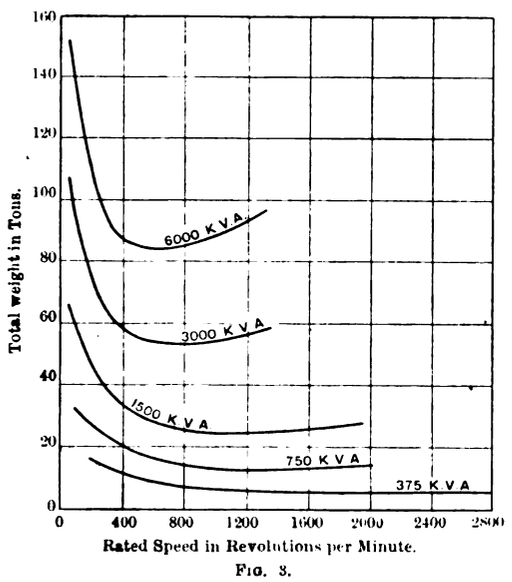

Fig. 3.

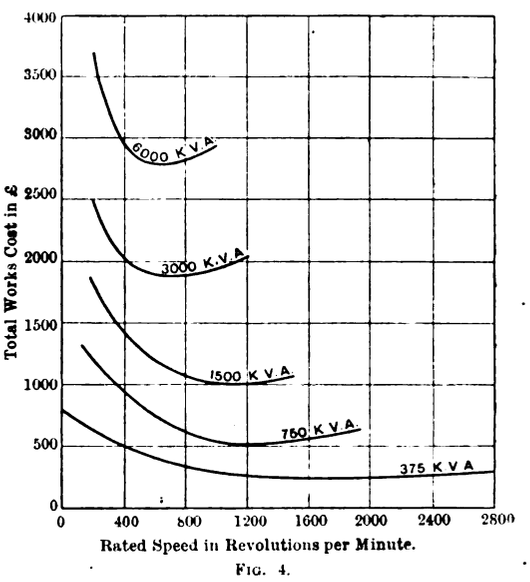

Fig. 4.

Figs. 3 and 4.—Curves for Total Weight and Total Works Cost of Alternating-current Polyphase Generators.

Continuous-current generators, however, are impracticable propositions at high speeds for rated outputs above 1,500 kw., and even for this rating continuous-current designs for pressures of less than 1,000 volts are relatively very unsatisfactory. Continuous-current generators for outputs greater than 1,500 kw. are, however, quite practicable for low and medium speeds when the terminal pressure is high, say 1,000 to 2,000 volts.

In comparing the designs for the purposes of the present investigation, two factors, namely, the rated voltage in the case of both C.C. and A.C. machines, and the frequency in the case of A.C. machines, have not

Digitized by Google

been taken into account. These factors may, and usually do, affect the design problem and the weight and cost to a considerable extent. Nevertheless, in the interests of simplicity, and so as not to complicate the present investigation by introducing too many variables, the author has taken the step of employing average representative values for each class of machine. The curves may be taken as roughly representative of the more customary ranges of voltages and periodicities.

In the case of alternators, nearly all designs—at any rate, for other than the smallest rated outputs—are for moderately high voltages. The voltage chiefly affects the design in that the greater the voltage, the greater is the amount of the armature periphery which must be devoted to slot insulation. Consequently a high-voltage machine has to be slightly larger than a low-voltage machine. Continuous-current designs, on the other hand, are rarely built for voltages greater than 1,000, and the space occupied by the slot insulation is a much less influential factor. For designs up

FIGS. 5–8.—CURVES FOR WEIGHT PER KW. AND COST PER KW. FOR CONTINUOUS-CURRENT AND ALTERNATING-CURRENT GENERATORS

to 1,000 volts, the chief difference between low and high voltage continuous-current machines relates to the commutator, which is larger and more expensive the lower the voltage, on account of the heavier currents which have to be collected. Although the actual commutator cost is a very appreciable item in the total works cost, nevertheless the difference in the commutator cost introduced by changing from, say, 250 to 500 volts is not so large a proportion of the total works cost as to prevent employing curves of rough values as representative of the customary range of pressures. Hence we may say that the curves in Figs. 1 and 2 are fairly representative for continuous-current machines of normal voltages. But we must bear these reservations in mind when using the curves for other than the customary range of pressures. In all the curves accompanying this article, *quantitative* values of the weight and cost are employed. It is not, however, to be understood that these values can have any wide application, since special conditions relating to the market price of labour and material, the intensity of competition and of "dumping," the manufacturing facilities of the firm building the machines, the skill of the designers, and the precise terms of the specifications to which the machines must comply, greatly affect these values. While it is the *relative* values which it is the purpose of this article to contrast, it has, nevertheless, appeared desirable to fix ideas by plotting the results to rough *quantitative* values, and the author has endeavoured to make these values reasonably representative.

The frequency, which only enters directly into alternating-current designs, is a more important factor. While the difference in weight and cost of, say, a 25- and 50-cycle design for a given rated output and speed, is quite appreciable, it has nevertheless been desirable in the present investigation to simplify the investigation by regarding the curves in Figs. 3 and 4 as applying to alternators of normal frequencies, say between 25 and 50 cycles. For a given rated speed the number of poles for a 50-cycle alternator is twice the number required for a 25-cycle alternator. Consequently, for a 50-cycle machine a larger armature diameter and a smaller armature gross core length than those for a 25-cycle machine of the same output are usually appropriate. The total weight of a 25-cycle machine is usually rather higher than that of a 50-cycle machine owing to the smaller number of poles and larger pole-pitch. Also where the speed is so high that four poles are required for the 50-cycle design and two poles for the 25-cycle design, the two-pole design is usually considerably heavier. In cases where the number of poles is small owing to the speed being high, the influence of the number of poles on the design is more marked than where the number of poles is great.*

Although the influence of these factors is considerable and presents an interesting study, nevertheless, in order to prevent these investigations from becoming too confusedly involved, the author has limited these comparisons chiefly to the two principal factors of rated output and rated speed. By this means several broad conclusions have been arrived at which would have remained obscure had it been attempted to take into consideration a large number of variables. We may,

* See *Electrical Engineering*, Vol. I., pp. 755, 831, 919, May 2nd, 1907, "The Design of Alternators as Influenced by the Rated Speed," H. M. Hobart and A. G. Ellis.

Digitized by Google

therefore, take the present investigation as applying to A.C. and C.C. generators of average pressures and frequencies, and designed to fulfil representative specifications.

It will be seen from the curves in Figs. 1 to 4 that there is a comparatively large range of speed for each rated output, for which the total works cost has practically a uniform value for A.C. as also for C.C. generators. There is, in fact, a certain rated speed for each rated output, for which the cost has a minimum value. Not only for lower, but also for higher speeds, the cost increases. At low and medium speeds, the weight and cost show a continued decrease with increasing speeds. This is, however, less marked the higher the speed, and is by no means in proportion to the speed.

The speeds shown by the curves in Figs. 1 and 2 to be the most economical as far as relates to manufacturing cost, are not the most favourable with regard to performance, their inferiority relating chiefly to commutation. Lower speeds than these, are distinctly to be preferred for continuous-current machines. A similar condition of affairs for A.C. generators is revealed by the curves in Figs. 3 and 4. There is, for each rated output, a certain speed at which the weight and cost reach minimum values. These most economical speeds are, as will appear later, higher for A.C. generators than for C.C. generators of the same rated output. High speeds are distinctly more suitable for A.C. generators than for C.C. generators, from the standpoint of manufacturing cost, and this is also most decidedly the case from the operating standpoint.

These points of minimum weight and cost will be observed for each rated output in the sets of curves in Figs. 1 and 2, as also in those of Figs. 3 and 4. It will also be noted that the most economical speed is greater the smaller the rated output. Here again, as in C.C. machines, there is a considerable range of speeds over which the weight and cost do not vary to any considerable extent. Even at the lowest speeds, where the effect of the speed is most marked, the variation of weight and cost is by no means in proportion to the change in speed. Thus, for example, a 1,500 k.v.a. A.C. generator at a rated speed of 200 r.p.m. weighs some 45 tons; at 400 r.p.m., which is double this speed, the weight is only reduced to some 33 tons; and a further increase of 100 per cent., viz., to 800 r.p.m., only reduces the weight to some 26 tons. The total weight reaches a minimum of 24 tons at 1,000 r.p.m. and increases again with increasing speed until at 1,600 r.p.m. the weight is again 26 tons, which is actually the same as at half this speed, viz., 800 r.p.m. Similar observations may be made for the other rated outputs, and also in regard to the Total Works Cost. For a given rated output in k.v.a. the Total Weight and the Total Works Cost per k.v.a. both decrease as the speed increases until the most economical speed is reached, above which both these quantities increase again. This is shown by the curves in Figs. 5 and 6, where are plotted the weight and cost per k.v.a. for A.C. generators. These curves are derived from the curves in Figs. 3 and 4. For low and medium speeds the weight and cost per k.v.a. rated output are lower the higher the rated output. It will be seen that the 6,000 k.v.a. curve is the lowest of the group, and that the 375 k.v.a. curve is the highest for speeds up to about 1,000 r.p.m. At high speeds, say above 1,000 r.p.m., the weight and cost per k.v.a. are higher the greater the rated output. Hence higher rated speeds are more suitable for machines of small rated output than for machines of large rated output. In other words, the larger the rated output the lower is the most economical speed.

It will be noted further that the weight and cost per k.v.a. at the most economical speed for a machine of 6,000 k.v.a. rated output, are smaller than for a machine of 3,000 k.v.a. rated output. For rated outputs below 3,000 k.v.a. the weight and cost per k.v.a., at the appropriate most economical rated speeds, are of about the same value. Thus the minimum weight per k.v.a. is about 13 kg., and the cost per k.v.a. some £0·45 (9s.) for a machine of 6,000 k.v.a. rated output as against some 15 kg. and £0·6 (12s.) per k.v.a. for a machine of 3,000 k.v.a. rated output and for ratings below 3,000 k.v.a. In Figs. 7 and 8 are given similar curves for continuous-current machines. The weight and cost per kw. are in this case derived from the curves in Figs. 1 and 2. These curves are of the same nature as those given in Figs. 5 and 6 for alternating-current generators. The weight and cost are, at *low* speeds, influenced to a fairly large extent by the rated speed, but when the region of high speeds is reached, the weight and cost are almost independent of the speed. In fact, the cost per kw. commences to increase again after a certain speed has been reached, as in the curves for A.C. generators. A point of considerable interest is that while the cost per kw. reaches a minimum, and commences to increase considerably again in this manner, the weight per kw. does not appreciably increase, but remains at a practically constant value.

CORRESPONDENCE

A COMPARISON OF THE BRITISH AND GERMAN ELECTRICAL INDUSTRIES.

To the Editor of Electrical Engineering.

Translation.

Sir,—Owing to the usual rush at Christmas time, I can only now write to thank you for your kind attention in sending me a copy of Electrical Engineering of the 17th inst., and also to acknowledge the excellent translation which you made of my last letter. There is much to say on the matter, but unfortunately the time cannot be spared for thoroughly testing the statistical material. That this latter is open to attack is evident from an article by Kurt Perlewitz in No. 51 of the *Elektrotechnische Zeitschrift*. The most important point to me, namely, the superiority which I claim for the German electrical industry, is incapable of mathematical proof; personal experience must give the result. But it is a fact that single-phase motors with high starting torque, metal filament lamps, electric driving of winding engines and rolling mills, high-speed motors for centrifugal pumps and flame-proof motors, and apparatus for mines (to name only a few of the most recent examples) have been practically developed earlier in Germany than they have in England. Wishing you a happy New Year, I remain,

Yours very faithfully,

Hugo Herzfeld (*Dipl. Ing.*).

11, Lützowufer, Berlin.
December 25th, 1908.

PRODUCTION OF NITRIC ACID BY ELECTRIC DISCHARGES.

To the Editor of Electrical Engineering.

Sir,—Allow me to point out that some of my remarks on Messrs. Cramp and Hoyle's Paper (see p. 813 of last week's issue) have been misunderstood. According to Rasch and Clement, no ozone (not resonance) is produced when the arc discharge takes place between electrodes of metallic oxides. Such electrodes, mostly Nernst glowers, are used by Haber and Koenig, who, in opposition to Nernst and most other investigators, recommend relatively cold arcs, believing with Warburg that both the thermal and the electric equilibrium have to be considered. I should like to add that my complaint about mixing up British and metric measures was not seriously meant, and that my remarks as to omissions were not made in any critical spirit. It is a pity that the authors cannot continue this promising research, and I said so.

H. Borns.

Chiswick, December 24th, 1908.

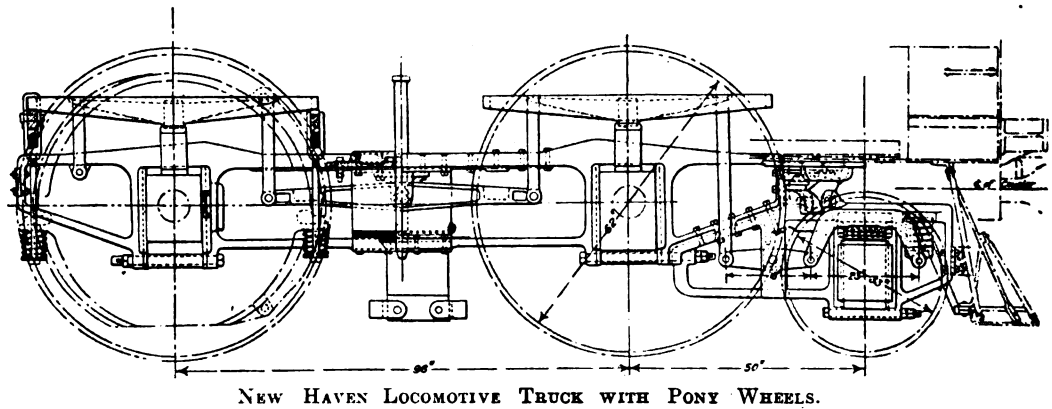
RECENT TENDENCIES IN ELECTRIC LOCOMOTIVE DESIGN

THE mechanical design of high-speed electric locomotives offers a problem of considerable interest and importance to the engineers of the present day, and in view of the rapid development of electric traction in America the following notes on the design of trucks for high-speed locomotives, abstracted from the *Electric Railway Journal* of New York, are of interest.

The first electric locomotives built for high-speed heavy electric traction in the United States were those of the New York Central. These locomotives had a long, rigid wheel base with four driving axles and a radial pony truck at each end. The motor armatures were built up on the driving axles, while the motor fields were supported on the frame. The driving wheels were only 44 in. in diameter, and were not connected with side rods or by any other means. Following this type came that of the New York, New Haven, and Hartford Railway with two separate four-wheel trucks carrying a motor on each axle. This type was fully described in ELECTRICAL ENGINEERING, Vol. II., page 408. An attempt was made to relieve the axles of the dead weight of the motor armatures by carrying the armatures on pins set into spring pockets in the driving wheel centres. These locomotives had no guiding wheels of any kind, the entire weight being available for adhesion. The driving wheels were 62 in. in diameter. The half-unit experimental single-phase locomotive built last year for the Pennsylvania Railroad, and which was tested at very high speeds, is the exact counterpart of the eight-wheel type of steam locomotive, long the standard for passenger service in the United States. It has two driving axles with wheels 72 in. in diameter, mounted in the main frame, and a swivelling four-wheel bogey truck in front. The method of supporting the motor armatures on "quills" mounted in spring pockets in the driving wheel centres is the same as that employed in the New Haven locomotives. The bogey truck carries 45,000 lb., which is nearly one-third of the total weight.



NEW HAVEN LOCOMOTIVE TRUCK WITH PONY WHEELS.

Since these three types of locomotives were built they have been thoroughly tested, and some modifications have been suggested. The New Haven is re-modelling all of its locomotives by the addition of a single pony axle placed in front of the driving wheels of each motor truck, as shown in the accompanying figure. The addition of these pony wheels, which are equalised with the main driving wheels, reduces the adhesion weight somewhat, but has resulted in a marked improvement in the riding qualities of the locomotives. The wheel arrangement of the locomotives is now represented by the following diagram: o O O—O O o. No important structural changes were required in the re-modelled locomotive cab or trucks in adding these pony wheels. The pony truck wheels are 33 in. in diameter, and are carried in a supplementary or extension frame bolted to the main truck frame. The outer ends of the supplementary frames are cross-connected by a heavy steel brace to keep them square. The supplementary pony truck frame being rigidly attached to the main truck frame, it was necessary to provide for some radial movement of the pony truck wheels. This is done by interposing a bevelled brass wedge over the journal box of the pony truck. The wheels, axle, and journal boxes of the pony truck are free to move laterally between the pedestal jaws of the supplementary frames, but in so doing they are met by the resistance of the bevelled bearing plate on top of the journal box. When the pony truck wheels move sidewise they lift through the bevelled bearing wedge all of the weight carried by the equaliser bars; this tends always to restore the pony truck wheels to their normal central position. The equalising system of the pony truck is connected to the equalising system which was formerly used on the motor trucks, but some modifications have been made in the original parts. In the illustration, immediately behind the third-rail shoe fuse-box, can be seen an equaliser bar hung from levers extending over the journal boxes of the main driving wheels. It will be noted that coil spring seats are formed on this equaliser bar. In the original construction, coiled springs were interposed between the top bar of the truck side frame and this equaliser bar on each side of the fuse-box. These springs have been removed and the journal box equaliser bar on the forward motor axle has been extended out, and to its outer end has been attached a hanger, which can be seen in the centre of the circular opening in the step riser A pivoted lever connects this hanger with the pony truck journal box equalising lever, which in turn is confined at its outer end by a small coil spring bearing against the top bar of the pony truck frame. In this manner all the wheels on one side are equalised. The brake gear of the motor trucks has not been modified in any way, as the pony truck wheels are not braked.

The twelve new locomotives now being delivered to the New York Central have swivelling bogey trucks at each end instead of a radial pony truck, and the side-thrust springs on the driving axle boxes have again been applied after being discarded on the experimental locomotive first built four years ago. Provision has been made for braking the main truck by hand in emergencies, and the bogey wheels are fitted with air brakes. The contact shoes have been removed from the main frame to the bogey trucks, where they can follow curves with greater ease. In the electrical equipment of the new locomotives, contactors are used for reversing instead of a reversing switch, as this brings about a slight reduction in the number of parts to be maintained. The General Electric Company has built a high-speed experimental locomotive which has two separate articulated trucks, each consisting of a pair of pony wheels at each end, with two driving axles in the centre. The driving wheels are connected with side rods. These recent developments in the mechanical design of electric locomotives indicate a tendency toward the sacrifice of adhesion weight for better riding qualities. One of the arguments advanced in favour of electric locomotives over steam locomotives some years ago was that the entire weight of the locomotive could be used for adhesion. In the light of the tendency toward the use of guiding wheels this argument no longer has weight. Theoretically, an electric locomotive having no unbalanced moving parts and exerting a fairly uniform tractive effort throughout each revolution of the wheels ought to be easier on the track than a steam locomotive, which actually lifts its wheels off the track when running at high speed, due to the unbalanced forces of the rapidly moving connecting and side rods. It has heretofore been assumed that "nosing" of a steam locomotive was due largely to the imperfect balancing, but this same action develops in the case of electric locomotives. A guiding truck of some kind seems to be necessary, but it is still a matter of doubt as to whether it is necessary to sacrifice such a large proportion of the total weight to load this truck sufficiently to hold it firmly to the track. The Pennsylvania locomotive carries nearly one-third of the weight on the bogey truck, while in the new locomotives of the New York Central the weight of the locomotive has been increased 20 tons, all of which is carried by the two bogey trucks, the adhesion weight remaining the same. This reduces the maximum hauling capacity of these locomotives by the amount of this extra weight, which means practically one car.

REVIEWS OF BOOKS

An Elementary Manual of Radiotelegraphy and Radiotelephony for Students and Operators. By Dr. J. A. Fleming, F.R.S. 340 pp. 9 ins. by 5¾ ins. Numerous illustrations. (London Longmans, Green & Co.) 7s. 6d.

In his preface the author explains that the book has been written for the benefit of students and practical operators, and for general readers, to whom the author's larger work might seem too advanced. The present is a much more modest work than the well-known large book, but besides being in character introductory to the older work, it is also to some extent supplementary, and will serve to bring its forerunner more nearly up to date.

The first chapter starts at once on the elementary theory of electrical oscillations, and describes broadly the conceptions and experimental facts of high-frequency resistance and high-frequency inductance of wires and circuits. Here are gathered the principal formulæ of utility in calculating the electrical constants of oscillatory circuits of known dimensions; and, besides, the rudimentary theory of resonance, tuning, and coupling is considered. The next two chapters are taken up with descriptions of apparatus and machinery for producing "damped" and "undamped" oscillations. We were surprised to find Prof. Fleming—usually so precise a writer—using the word "undamped," which if it has a meaning at all, is an erroneous one. Both chapters are wholesomely practical, and the second one of the two, which deals with the arc, is well up to date. Chapter IV. deals with the theory of electromagnetic waves. Unfortunately, however, the theory is not always quite sound; for example, we are told that "the expression *curl* signifies the line integral round a unit of area." Chapter V. treats of radiating and receiving aerials, and emphasises the importance of conductive connection with the earth; and Chapter VI. passes to the consideration of oscillation detectors. Here the physics of various detectors is briefly and clearly discussed, but no quantitative comparison of their capabilities as receivers of wireless messages is given, though, of course, the practical performance of a detector is pre-eminently the thing about it worth knowing. In fact, the author lumps together all sorts of detectors without giving any proper notion of their comparative sensitiveness in signalling; and actually devotes several pages to minute descriptions of old detectors that have never detected. On the other hand, the author gives no hint of how to set up for work any of the important modern detectors, such as the crystal rectifiers.

In Chapter VII. we come to the description of commercial radiotelegraphic systems and stations. Chapter VIII. returns to the laboratory, and gives methods of measuring capacity and inductance, wave-length and damping-factor. Much of the matter is from the author's larger treatise; and we note that in repeating the diagram of the Anderson bridge the opportunity has been taken of correcting a misprint.

The last chapter, on radiotelephony, is a very fair and compact statement of the recent progress of that art. We notice, however, one error of some importance. The illustration on page 327, which is offered as a picture of the receiving apparatus in Poulsen's method of wireless telephony is, as the looseness of the coupling shows, an ordinary telegraphic receiving set. In connection with this particular apparatus we might mention that the statement in the text that Poulsen used a crystal rectifier is also misleading.

Looked at broadly, the book is a sound and comprehensive presentation of the laboratory side of wireless telegraphy, and is one to be warmly commended to the strictly technical man. Its appeal to the "general reader" mentioned in the preface is but slight; for the author does not appear to feel in any degree whatever, the glamour his subject possesses for the layman. As for the wide circle of scientific followers of wireless telegraphy, we think they will be disappointed by the complete absence of disinterested suggestion for improvements, and of forecasts as to the direction of future progress.

Elementary Dynamo Design. By W. Benison Hird. 276 pp. 8½ in. by 5¼ in. 128 illustrations. (London: Cassell and Co.) 7s. 6d.

Some of the works of Aristotle are reputed to be notes of his lectures edited by grateful disciples for the benefit of posterity, but the fashion is now changed, and it is the lecturer who himself publishes his notes in book form for the benefit of his pupils. So long as this fashion continues, there will be no dearth of such books as the present. Yet "Elementary Dynamo Design" is a favourable specimen of its class; it is written in a simple and lucid style, with practical knowledge, and it does not err from over-ambition; no attempt is made to go into any of the minutiæ of design, which would appeal only to the scientific or to the proficient designer, and a good sense of the relative proportion between the various parts of the subject is preserved. After a preliminary chapter on general matters, different types of armature and field-magnet windings are considered. The subject of continuous-current dynamos is then taken up in detail, and followed by that of continuous-current motors. A dynamo to give 500 volts, 200 amperes at a speed of 420 r.p.m. is designed throughout, as also a motor to give 10 h.p. at 600 r.p.m. Other specialities, such as variable-speed motors, crane and traction motors, commutating poles, compensating winding, and Sayers' commutator connections are shortly described. Alternate-current machinery is then treated in a similar manner, a general chapter being followed by the complete designs of a three-phase generator to give 300 kilowatts at 2,000 volts, with a frequency of 25 and a speed of 375 r.p.m., and of a three-phase motor for 100 h.p. 500 volts, and 500 r.p.m. The synchronous motor and single-phase motor are briefly described in the final chapter.

Though the book is, so far as it goes, unimpeachable, yet it may be questioned whether there is sufficient justification for its appearance in a field which is already well-covered. The author of a new technical book should either have something original to say, or must bring to an old and well-worn subject some new point of view, method of treatment, or quality of lucidity which is not to be found in his predecessors. In the present book it would be hard to find anything which has not been said before and said in much the same way.

Elementary Manual on Steam and the Steam Engine. By Andrew Jamieson. 12th edition. 355 pp. 7½ in. by 5 in. (London: Charles Griffin & Co.) 3s. 6d.

This, the twelfth edition of Prof. Jamieson's well-known elementary text-book on the steam engine, differs but little from the previous edition, with the exception of minor corrections and the addition of recent examples of examination papers. At the time of the eleventh edition, two years ago, the work was thoroughly brought up to date, and many drawings and descriptions relating to thoroughly modern practice, especially with regard to steam turbines, were added. The principal object of the work is, as is well known, to provide an elementary manual for the use of students preparing for certain examinations, and generally to form an introduction to the study of steam engineering as covered in greater detail by the author's

Digitized by Google

larger works, and its success in achieving this purpose is evident from the editions which have been called for. The subject is divided into 19 chapters in the form of lectures, to each of which is appended a series of questions, and, of course, the relative amounts of space given to the theoretical and the practical, and likewise the degree of absence of mathematic knowledge assumed on the part of the reader, are governed by the requirements of the examinations in connection with which the book is intended to be used.

The Elementary Theory of Direct-Current Dynamo Electric Machinery. By C. E. Ashford and E. W. E. Kempson. 120 pp. 7½ in. by 5 in. 73 illustrations. (London: Cambridge University Press.) 3s.

The authors of this little book have not followed the course taken by so many writers of so-called elementary works on the dynamo of trying to give to the student a single small work which shall make him not only a fully-fledged dynamo designer, but also a living catalogue of semi-obsolete commercial machines, but have endeavoured to provide just such a clear presentation of the principles upon which the subject is based, a due study of which may enable the student to understand any piece of electrical machinery which he comes across, not because he has ever seen or heard of it before, but because he can recognise it as a particular case of a general class the fundamental principles of which he has mastered. The course of reasoning is logical and clear, and is entirely free from that looseness of expression degenerating into inaccuracy which disfigures so many text-books. One of the few criticisms to make is that the idea of self-induction might have been introduced to the reader a little earlier in the book. The set of examples at the end is admirably chosen, and a well-arranged index is provided.

The Management of Dynamos. By G. W. Lummis-Paterson. Fourth edition. 285 pp. 7½ in. by 4¾ in. 117 illustrations. (London: Crosby, Lockwood & Son.) 4s. 6d.

This is the fourth edition of this book, which was first published in 1895, and, as the author states in his preface, the construction of electrical machinery has undergone radical changes during the thirteen years that have elapsed since then. The task of revising the work was therefore no easy one, and the result shows that the author would have been better advised had he written an entirely new work. The first three chapters, dealing as they do with merely the elements of electricity and magnetism, are not out of date, but the same cannot be said for other portions of the book.

The Deinhardt-Schlomann Series of Technical Dictionaries in Six Languages. By Alfred Schlomann. Vol. IV.: Internal Combustion Engines. 618 pp. 7 in. by 4½ in. (London: Archibald Constable & Co.) 8s.

The present volume of this series of technical dictionaries is arranged in the same convenient manner as the previous volumes which we have had occasion to review from time to time, that is to say, the ideas are arranged according to subject matter with the German, English, and French expressions on one side of the page, and the Russian, Italian, and Spanish on the other, while suitable illustrations are given in the central space. The latter part of the book consists of alphabetical indices with the Russian words separately, owing to the difference in alphabet. The internal-combustion engine is dealt with in the same elaborate detail that characterised the treatment of the steam engine in the previous volume, and, as is natural for a publication originating in Germany, the illustrations relate principally to the large slow-speed pattern of gas engine. There is, however, a good deal in the volume the connection with which to the internal-combustion engine is but remote, and, as in the former volumes, a good many obvious phrases made up of non-technical words, which no one would look for in a technical dictionary, are included. It is better, however, in a work of this class to err on the side of over-completeness than incompleteness.

Field Telephones for Army Use. By Lieut. E. J. Stevens. 110 pp. 7¼ ins. by 4¾ ins.; 67 illustrations. (London: Crosby, Lockwood & Son.) 2s.

At the risk of being called "old-fashioned," we maintain that correct grammar and accuracy of expression are essential in an elementary book dealing with a technical subject. Lieut. Stevens' book falls lamentably short in this respect. We accept his opinion that officers and non-commissioned officers will welcome a work explaining the principles of field telephony, and we trust that the demand for the present production will be so great that the faults in style, grammar, and arrangement may shortly be remedied in a second edition.

HEAT LOSSES IN ELECTRIC POWER STATIONS

At a meeting of the Institution of Civil Engineers on Tuesday, December 22nd, a Paper by Mr. F. H. Corson, entitled "An Investigation of the Heat Losses in an Electric Power Station," was read. The following is an abstract of the Paper:—

An inquiry, originating from Blackburn, in 1903, showed that the average coal consumption of thirty-four principal generating stations of the United Kingdom was about 7·7 lb. per unit generated. The figures ranged from 3·6 lb. to 15 lb., Blackburn standing at 10 lb. Rough tests on the various sections of the plant resulted in considerable rearrangement. The steam-pipe system was overhauled and more effectively drained, and steam separators and driers were in consequence dispensed with. Engine stop valves were, where possible, attached directly to the main steam-pipes. The steam-ring was discarded, and generally the effective heat-radiating surface was greatly diminished. Better fitting boiler dampers were provided, the condition of the brickwork was improved, and the whole process of combustion was more thoroughly controlled by the institution of flue-gas analysis. These and similar alterations occupied about three years, and the fuel-consumption fell during that time to about 6 lb. of the same coal per average unit generated, a reduction of 40 per cent. Further progress being imperative, it was decided to conduct tests covering the whole operation of the works, viewing the losses peculiar to each part of the plant in their relationship to each other and to the whole; and arrangements were made, and apparatus devised, for their prosecution. After isolated trials of the various types of apparatus had proved their reliability, simultaneous tests were arranged of a duration long enough to embrace all conditions of operation met with in routine work.

The Blackburn undertaking comprises two adjoining stations of 2,300 kilowatts capacity each, containing twelve mechanically-fired Lancashire boilers, six fitted with superheaters; fifteen high-speed engines driving generators from 60 kilowatts to 775 kilowatts in size, controlled from three switchboards; steam piping 3 in. to 14 in. in diameter; ejector and jet-condensers fed from an overhead water-tank above the boiler-house; low-speed steam-driven feed-pumps; four batteries of economisers totalling 1,504 tubes; two chimneys, 150 and 250 ft. high respectively. The test has covered during 168 consecutive hours the combustion of about 230 tons of coal, the evaporation of 3·376 million pounds of water, and the generation of 99,295 electrical units. The net results show a consumption of 5·15 lb. of coal, and a total evaporation of 33·9 lb. of water per average unit.

Observations have been taken half-hourly of the rate of evaporation, and of the temperature of the feed-water at the feed-tank, and the economiser inlets and outlets; of the chemical composition and temperature of the gases in boiler and economiser flues; of the temperature and pressure of steam supplied to and discharged from the engines; of the temperature and quantity of the injection and discharge water of the condensers; and of the electrical units generated. Some of these data have also been obtained by using recording apparatus. The performance is shown on a time basis in curves, and in total in eight balance-sheets relating to the operation of the whole plant and of its constituent parts. So far as possible, the results have also been entered on the form prescribed by the Institution Committee on Steam Engine and Boiler Trials.

New R.E. Wireless Telegraph Station.—A contemporary states that a station is being erected at the Claypit Lane Barracks, Leeds, in connection with the Northern Command Telegraph Companies (Royal Engineers). A wireless telegraph company has been formed under Captain F. E. Johnson, and it includes over sixty non-commissioned officers and men, including amongst their respective callings telegraph operators, electricians, engine drivers, and fitters. Sergeant J. Brown, of the Aldershot School of Wireless Telegraphy, has been attached as instructor. With the apparatus installed it will be possible to communicate with coastguard stations, war vessels in the North Sea, and, it is hoped, Aldershot—a distance, roughly, of about one hundred and sixty miles. The company will also be supplied with a portable station for field work.

"Wireless" Weather Reports.—The Meteorological Office has made arrangements with the shipping companies owning ships on the Atlantic routes, whereby the former will receive weather reports by wireless telegraphy. In order that the position of the ship from which the report is sent may be readily identified, the Atlantic Ocean is divided into imaginary numbered areas, and the number of the area from which the report is sent is included in the message. The Meteorological Office will thus be provided with much more complete information regarding the weather conditions to the westward than hitherto.

THE COST OF ELECTRIC HEAT

(By a Correspondent)

THE processes to which electrically generated heat can be applied in this country are limited to those in which its superiority in temperature control and effectiveness of application render it either unique in some particular or more efficient as regards cost than heat obtained directly from fuel, whether solid, liquid, or gaseous. In localities, however, where large quantities of cheaply developed water-power or other sources of cheap power are available, the conditions are now such that the commercial utilisation of electric heat may afford the only means of development of the natural resources of those localities. Very little consideration serves to show, moreover, that the number of uses to which it can be put, even in this country, where fuel is so cheap, are not fully realised.

Theoretically the electrical h.p.-hour is equivalent to about 2,545 British Thermal Units, and, if the assumption be made that the load-factor necessary for the best conditions for power generation can be attained, one may expect, on a reasonably large scale, to obtain this quantity of heat for a consumption of 1 lb. of high-class coal, the calorific value of which may be taken as 15,000 B.Th.U., with an efficiency of conversion therefore of 2,545/15,000, or, in round figures, 17 per cent. Remarkable and difficult, though not impossible of attainment, as this efficiency is, the conclusion leaps to the eyes that, when the capital costs involved are considered, it is only in cases where the losses of heat in the direct furnace are extremely high, or where exceptional conditions of temperature or of control are necessary to the process using the heat, that fuel-generated electrical heat can be considered a commercial proposition. That such conditions exist, however, is proved by the increasing use of the Kjellin, Héroult, Stassano, and other electric furnaces for a variety of purposes, and it cannot be questioned that as investigators widen their field of experiment further uses will be found. As regards ease of control and in cases where very high temperatures are not required, the gas furnace must, however, continue a formidable rival to the electric furnace.

Our knowledge of the subject has now so far advanced that installations for the utilisation of electric heat can be developed on sound engineering lines, and with no element of risk of technical failure, so that, given the condition that coal is dear and water power, or power from waste gas, relatively cheap, in any locality electrical heat is, *cæteris paribus*, the only commercially possible proposition. It is impossible to generalise, as each case must be treated on its own merits, every influencing circumstance, such as the use to which the heat is to be put, the cost in the locality of raw material for the process in contemplation, and the situation of the power with regard to the markets, being given its own place in the general scheme. But it is of interest to bear in mind that, if we assume equal efficiency of application (an assumption generally greatly in favour of fuel), we can arrive at a basis of comparison. The "electrical h.p.-year," which cumbrously expresses a quantity of work, is equivalent to $2,545 \times 24 \times 365 = 22,300,000$ B.Th.U. (nearly). If we take the thermal value of 1 lb. of coal, as before, as 15,000 B.Th.U., we get the coal equivalent of the h.p.-year, $22{\cdot}3 \times 1,000,000$ 15,000 = 1,485 lbs. (nearly), or 0·005 ton. Thus, if the money value of the h.p.-year obtained from water power, waste gas, or other cheap source is in any locality less than that of 0·67 ton of coal of a thermal value of 15,000 B.Th.U., plus the cost of making the heat in it available, then, other things being equal, it is more economical to make use of electric heat. As has been remarked, however, the greater efficiency of application of electric heat makes this figure in general greatly favourable to coal. As illustrating this point the following is of interest.

The electrical work done in refining one ton of steel of the crucible class appears to be from 0·13 to 0·17 E.H.P. years, say, an average of 0·15 or $3{\cdot}36 \times 1,000,000$ B.Th.U. On the other hand, in crucible-steel making by the ordinary method about three tons of coke, which may have a thermal value of 14,000 B.Th.U. per lb. are required, or a total $3 \times 2.240 \times 14.000 = 94{\cdot}2$ million B.Th.U., or 28 times as much heat per ton as is absorbed by the same process carried out electrically. In other words, if the heat usefully applied in the electric furnace be taken as 80 per cent. of that supplied (it is difficult at present to find figures on the point), then the heat wasted in the crucible process must be about 97 per cent. of that supplied, and the lower the assumed efficiency of the electric furnace the greater the loss in the ordinary process works out. Even under English conditions this astonishing heat saving ensures the future of the electrical method. It is said that in regenerative crucible furnaces the fuel consumption is reduced to one ton, but even so, the heat wasted amounts to 91 per cent. of the whole, on the same basis. The case shows what has already been done in the matter of heat economy by electrical means, and indicates what may be expected in the future in other directions.

The cost of heat obtained from burning coal, on the theoretical basis, varies in this country according to the cost of the coal and its thermal value from 4d. to 7d. per million B.Th.U. The lowest published cost of generating energy is somewhat under ½d. per kw.-hour, and this is equivalent to about 12s. per million B.Th.U.; on the large scale about one-half of this might be represented by fuel, or say, 6s. per million B.Th.U., or 13 to 26 times the cost of the same heat given to the boiler by burning the fuel in its furnaces. It has to be borne in mind, however, that figures such as have been quoted are obtained from plants not primarily designed to deliver electrical heat and working on a load factor of from 15 to 20 per cent., whereas the first aim in the arrangement of electric furnaces is to ensure that the source of power shall work at its full capacity at all times, which would very materially reduce this cost, in many cases so far as to enable the electric furnace with its vastly superior efficiency to compete successfully with the directly burnt fuel. In considering the cost of fuel-generated electrical heat, it has also to be remembered that the reiterated statement that the cost of electrical supply is entirely a matter of capital, is only to a limited extent true. There is a certain irreducible minimum representing fuel cost, and the better the capital involved is utilised the more closely does the total approximate to this minimum and the larger does the proportion of cost due to fuel become. It is thus unlikely that a large power scheme, handicapped with distribution costs, could successfully compete with a relatively insignificant heat plant working on a 100 per cent. load factor.

In localities where blast-furnace gas is available, the conditions are still more favourable to electric heat. A blast-furnace is said by Gruber to produce gas in such quantity that, after the requirements of the works have been met, about 23·5 h.p. per ton of pig produced in 24 hours is available externally, the thermal value of the gas being taken by him as about 101 B.Th.U. per cubic foot. This figure is probably too high, as an average, and it is safer to figure on 70 B.Th.U. per cubic foot, equivalent to 16·5 h.p. per ton produced in 24 hours, or for a furnace producing 100 tons, 1,650 h.p. From this, taking the efficiency of the electric generators as 90 per cent., we can do electrical work at the rate of nearly 1,100 kw., or in the 24 hours 26,400 kw.-hours = 90·0 million B.Th.U., the cost of this heat being the cost of making it available, the fuel being obtained without cost. Now, if the capital cost of making this power available be taken as £20 per kw., a reasonable figure, and the annual capital charges 12 per cent. on this sum —leaving wages out of consideration as being assumed the same in the two cases—the cost for the 1,100 kw. for the day would be £7·3, or about 0·133s. per kw. per day, which is equivalent to 1s. 5½d. per million B.Th.U., or three times the average cost of the theoretical heat to be obtained from burning coal.

In localities where cheap water power is available and a demand for heat exists, or can be created, the conditions are most favourable of all. But it is important to recognise the fact, so often overlooked, that water power is not necessarily cheaper than other sources of power, whether it is so or not depending upon the cost of making a regular output available, this cost varying enormously in different watercourses. Thus, for instance, in Scandinavia the cost of the "electrical h.p.-year" varies, according to circumstances, from 33s. to about 220s., or from 1·47s. to 9·85s. per million B.Th.U. Equally low costs have been attained in Italy and in Switzerland, but in America the average cost appears to be materially higher than in Europe. Obviously, however, from what has been said it is clear that the superior efficiency of the electric furnace should render electric power under conditions making in any way possible the lower of the above-mentioned figures, or anything approaching it, a very much cheaper source of heat than any other. Naturally the cheaper water powers have been, in the majority of cases, long ago equipped for various purposes, but there still exist, within the knowledge of the writer, large undeveloped Scandinavian falls which have been thoroughly investigated by competent engineers and shown capable of producing power at an exceptionally low rate.

Metallurgical uses of electric heat are increasing year by

Digitized by Google

year, and in them will doubtless the largest developments take place, but there would appear to be a large field for its application in those cases where a closed chamber contains the object to be heated, the heat being transmitted from without inwards through the walls of the chamber, such as pottery ovens, and kilns, bakery ovens, and so on. It has been calculated, for instance, that in certain types of pottery kilns in regular use, the total mass of material actually heated is about 100 times that of the mass of the material that is the object of the heating, a large part of the body of the kiln attaining a much higher temperature than its contents.

In these cases it is, of course, essential that flame and products of combustion should be entirely isolated from the object to be heated, and electrical heat, chemically clean, capable of accurate control, and of application exactly where it is wanted, would seem to fill all the requirements of the case, even though the cost of the electric power employed be not the lowest possible.

CARBON BRUSHES FOR TRACTION MOTORS

THE American Street and Interurban Railway Engineering Association, at a recent meeting held in New York, discussed a report on carbon brushes for traction and other motors, which had been prepared by a Special Committee on the maintenance and inspection of electrical equipment. In the report, an abstract of which was given in a recent issue of the *Electrical World* (New York), motor brushes are classified under three different types, namely, coke, part coke and part graphite, and graphite. Assuming this classification, the report states that coke brushes are generally suitable for railway motors of approximately 50 h.p. and less, with ungrooved commutators operating on low-speed service, such as city service, shunting locomotives, air compressors, or other service where the abrasive and polishing quality of the brush is necessary. The composition of the brush is mainly coke. By ungrooved commutators are meant commutators in which the mica insulation between the segments extends to the surface of the commutator. Part coke and part graphite brushes are generally suitable for motors of 50 to 100 h.p. in interurban and suburban service, and are normally used with grooved commutators. Should the commutator require only a moderate amount of abrasive effect to keep polished, these brushes may operate on the above sizes of motors without the mica being grooved. Since a commutator having grooved mica requires less polishing effect, this brush may be used to considerable advantage on motors of less than 50 h.p. in city or low-speed service, provided the commutators are grooved. Graphite brushes are suitable for general use on grooved commutators and on motors of 100 h.p. and over. The graphite brush inherently has large lubrication properties, and has the power of carrying a large current per square inch. The lubricating quality of the graphite brush serves to reduce or obviate chattering and constant breakage of brushes. The abrasive effect of graphite brushes is generally low; they have not the power to polish the commutator and wear away the mica, and therefore should be used only on commutators with grooved mica. The composition is mainly graphite.

A mechanical test is recommended in the report for the purpose of determining the strength and hardness of the brush, and an electrical test for the purpose of ascertaining the current the brush is capable of carrying before glowing, is also proposed. The abrasive effect, while very important, is not definitely set forth in the report for the reason that it has not been possible as yet to find a short, concise method of determining this effect.

In the mechanical test the brush is subjected to a series of mechanical shocks to determine how tough or brittle the brush may be. The vibrator consists of a ratchet wheel, with a diameter of 8 in. There are eight teeth, the depth of each tooth being $\frac{1}{8}$ in. Adjacent to the wheel a standard brush-holder is mounted so as to allow the brush to bear on the wheel with a standard pressure of 7 lb. per square inch of the bearing surface or cross-section of the brush. The speed of the ratchet wheel should be 250 r.p.m. With this speed the brush will receive 2,000 blows per minute. The ratchet wheel revolves backward so as to slip under the brush, and drop the same down $\frac{1}{8}$ in. as each tooth passes. It has been found that a brush which breaks badly in service will hardly run on this wheel more than 5,000 revolutions, and one which is fairly satisfactory in service will run 20,000 to 50,000 revolutions. A brush which is of excellent mechanical quality will run 100,000 revolutions and show no breakage or chipping. It is suggested that coke brushes should stand 20,000 revolutions on the vibrator wheel; part coke and part graphite brushes, 30,000 revolutions; and graphite brushes, 50,000 revolutions.

In the electrical test the current is passed through the brush to a slip-ring to determine the maximum amperes per square inch which the brush can carry without glowing. The slip-ring should be a wheel of hard copper 8 in. in diameter, $\frac{1}{2}$ in. thick, with a width of face sufficient to test the widest brush. The speed of the slip-ring should be approximately 500 r.p.m. The pressure per brush should be 7 lb. per square inch of bearing surface or cross-section. The periphery of the slip-ring should have a true and smooth surface. Twelve or fifteen samples of each quality of brush should be tested. The current should pass from the brush to the slip-ring. The maximum of 25 volts will be suitable for testing ordinary railway brushes. The following requirements are suggested :—Coke brushes, 100 amp. per square inch without glowing; part coke and part graphite brushes, 150 amp. per square inch without glowing; graphite brushes, 200 amp. per square inch without glowing.

In the discussion on the report, Mr. E. GINDRE (Le Carbone Company, of Paris) said that he considered a good brush should show a fracture of uniform appearance both crosswise and lengthwise, and must be free from shrinkage cracks. He did not think that the vibrator test corresponded closely enough with the conditions of practice. He considered the slip-ring test a valuable one. An important feature of every carbon grade is its friction coefficient, and the friction losses should be measured. The rational abrasion test would consist in running different brushes on a soft material, the wear of which measured by the decrease in weight would be proportional to the abrasive coefficient.

Mr. E. T. MUNGER (member of the Committee) said there had been some objections made to the vibratory test, and the Committee had agreed to reduce the depth of tooth from $\frac{1}{8}$ in. to 1-16 in., and to increase the diameter of the wheel from 8 in. to 9$\frac{1}{4}$ in.

Mr. H. H. ADAMS (New York City Railway) pointed out that the brush must fit properly when testing for the current that will make the brush glow. With the vibrator wheel, if one brush is destroyed at 10,000 revolutions and another at 50,000 revolutions, the inference should not be drawn that one will last five times as long as the other, as the vibrator test as proposed is not a correct measure of the service.

Mr. BRADY (National Carbon Company) thought that most of the tests advocated were laboratory tests. Carbon, being of a cellular structure, has only a few points of contact, unless extreme care is taken in working the brush down to a true surface. This is one point which gives trouble, particularly on the slip-ring test, which is more a matter of contact resistance than anything else. A brush with a high contact resistance will glow more quickly than a brush with a low contact resistance. A brush with a high contact resistance is a good brush to have in some cases, while one with a low contact resistance is good in other cases. It is all a question of the fit of the brush. In his own laboratory slip-ring test he found it necessary to run anywhere from 24 to 36 hours steadily on a smooth wheel to get the brush down to a true surface.

Mr. WINSOR thought the vibration tests were a step in the right direction. The Committee did not recommend a standard of how many vibrations a certain brush should make, but said that under certain conditions if it was found able to make 20,000 revolutions before breaking, it will stand up under certain conditions.

A New Primary Battery.—A new form of double-fluid zinc-carbon battery has been brought out by Mr. W. A. F. Bleek, of Brisbane. An E.M.F. as high as from 2·5 to 2·7 volts is claimed for the cell, which is stated to be suitable for giving current continuously for long periods.

Charges for Wireless Telegraphic Messages in Germany.—The charges for wireless telegraphic messages at the German coast stations are as follows :—Besides the regular telegraph rates in Germany of 5 pfennigs (0·6 pence) a word, minimum price 50 pfennigs (6·0 pence), there is a charge of 15 pfennigs (1·8 pence) a word, minimum 1·5 marks (1s. 6d.), and if the message is sent to a steamer which can be reached from the coast station an additional toll of 35 pfennigs (4·2 pence) a word, minimum 3·5 marks (3s. 6d.), is charged. An international list of wireless telegraph stations and their governments is now being prepared by the International Wireless Telegraph Bureau at Berne, but it has not yet appeared. Until this list, which is to contain the charges for sending wireless messages, is published, the fee for coast stations outside of Germany, according to information obtained from the *Gesellschaft fur Drahtlose Telegraphie* of Berlin, has been fixed at 48 pfennigs (5·9 pence) a word, with a minimum of 4·8 marks (4s. 10d.). If the fees at the said coast stations are in excess of those stated in the new list, the difference will be returned to the senders when the new list goes into effect.

EXHAUST STEAM TURBINES

A PAPER entitled "The Utilisation of Exhaust Steam in Low-pressure Turbines" was read by Mr. R. F. Halliwell before the Rugby Engineering Society at the last meeting before the Christmas recess.

The author mentioned that as long ago as 1837 a patent was taken out by Sir James Anderson for a turbine to utilise the exhaust steam from a reciprocating engine to which the turbine was to be connected by means of a belt; in 1846, also, Sir H. Bessemer took out a patent for a somewhat similar apparatus, but there seems to be no record of such machines having been actually constructed. The first exhaust steam turbine to be put in practical operation in the British Isles would appear to have been made by the Hon. C. A. Parsons in 1902; while abroad an exhaust steam turbine plant designed by Professor Rateau was installed in the same year at the Bruay mines in France.

Some curves were then given showing the thermodynamic features of the expansion of steam, and it was argued that theoretically the most economical system would be a combination of reciprocating engines to deal with the high-pressure steam, and turbines to receive the steam at a suitable pressure, and extract the remaining available energy. In the case of a new installation this system is generally impracticable, and the putting down of turbines alone is preferable. In the case of existing reciprocating plants quite a different case is presented; it only remains to add the low-pressure turbine to obtain, at small additional capital cost, a combination that will add from 30 per cent. to 80 per cent. to the capacity of the plant with the same amount of steam.

The applications of exhaust-steam turbines to reciprocating plants may be divided broadly into three main classes. Those in which the supply of exhaust steam is continuous and practically constant in amount; those where the steam supply, although continuous, is liable to vary in quantity; and those where it is intermittent.

In the first case it is generally found that the output required from the turbine is also practically constant, and all that is required is a relief valve to discharge surplus steam, and possibly some form of reducing valve to admit high-pressure steam on occasions when the exhaust steam may be insufficient. In the second case, it is usually necessary to instal a turbine of a mixed pressure type, having high pressure stages, in which the live steam may do work and keep the turbine running during the periods of insufficient supply of exhaust steam, without loss of energy entailed by the use of a reducing valve. This complication is, however, not required when the work consists of the supply of electrical power, and the reciprocating engine and turbine dynamos can be connected in parallel, as under these circumstances the supply of steam to the whole plant is controlled by the governor of the reciprocating engine.

In the third case, examples of which are rolling mill engines and colliery winding engines, neither of the above systems are suitable. To get over the difficulty, Professor Rateau designed an accumulator to store up the surplus heat supplied when the engines are running, and deliver it in the form of steam when the engines are stopped. This he accomplished in his early form of accumulator by providing a closed vessel, through which the exhaust from the engines passed, which contained a large number of heavy cast-iron trays filled with water. The exhaust steam circulating among the trays condensed, and in doing so gave up its latent heat, thus raising the temperature of the cast-iron and the water in the trays. As long as the supply of exhaust steam was in excess of the quantity required by the turbine, the pressure and temperature in the vessel would increase up to the limit fixed by the relief valve. When the supply of steam stopped, the turbine still drawing out its required amount, the pressure and temperature in the steam space would gradually fall, causing the water in the trays to evaporate by reason of the higher temperature of the water and the cast-iron. Professor Rateau also employed another type of accumulator, in which the heat-storing medium consisted of scrap rails stacked inside a boiler shell, with spaces between the rails to permit the steam to circulate. A scrap-metal accumulator of this latter type has been installed at Hucknall Torkard Colliery; it is 6 ft. in diameter and 24 ft. long, and contains 50 tons of old rails, and supplies a 175 h.p. Rateau turbine during engine stops of 40 seconds.

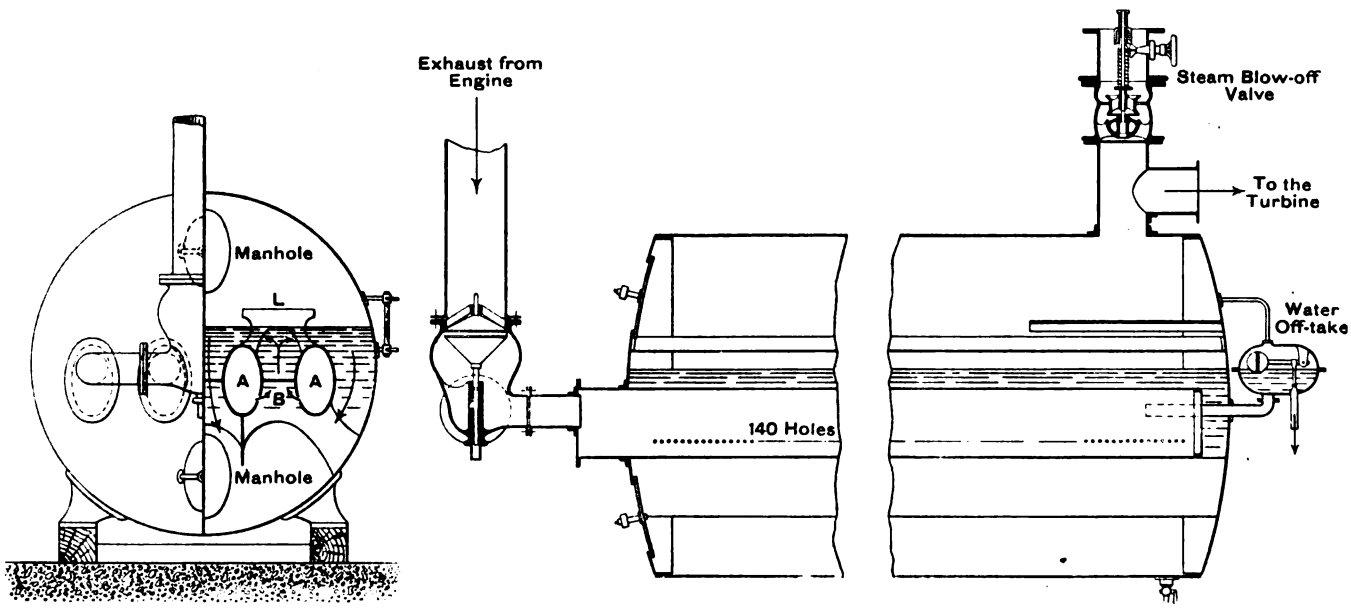

FIG. 1.—RATEAU ACCUMULATOR, LATEST WATER TYPE.

As the specific heat of water is about nine times that of iron, any form of iron accumulator is very heavy and expensive, and their use has been practically given up in favour of those which depend solely on water.

In the latest Rateau water accumulator, shown in Fig. 1, the horizontal shell is fitted with longitudinal flues of oval section, with the major axis vertical or of inverted U-shaped section; these flues are placed with their tops about one foot below the water-line, the accumulator being about two-thirds full of water. The exhaust steam is admitted to the flues and escapes through numerous holes in the vertical sides, and rising to the surface, establishes a vigorous circulation upwards, baffle plates being arranged to guide the water back again to the bottom of the accumulator. By this means practically the whole body of water in the accumulator is brought into the path of the steam, a condition which is absolutely essential if the temperature of the water is to be raised to correspond with the pressure, as otherwise the surplus steam would not be condensed and would escape through the relief valves.

Another form of accumulator which is coming into use is that patented by Messrs. Louis Schwarz & Co., of Dortmund. The steam is not forced through the water, but the necessary amount of water is pumped to the top of the accumulator and exposed as efficiently as possible to the action of the steam. The accumulator consists of a vertical shell with several diaphragms, each with a large number of short tubes projecting upwards;

Digitized by Google

water lies on the diaphragms to the height of the tubes and also for a few feet at the bottom of the accumulator, whence it is continuously pumped up to the space above the top diaphragm by a small centrifugal pump, and overflowing down the interior of the successive sets of tubes, a large surface is exposed to the heating action of the steam. The steam is led to the bottom chamber of the accumulator and rises through the tubes to the top chamber, where is situated the relief valve and outlet pipe. It is stated that the power required to drive the pump is a very small percentage of the total power developed by the exhaust steam. A similar loss occurs with a Rateau accumulator through having to force the steam through the water. An interesting patent has been taken out by Mr. Samuelson, of the B.T.-H. Co., for a form of accumulator which has no such loss inherent in its design. This is simply an application to steam of the ordinary gasometer, with the necessary modifications. It consists of a bell to contain the steam with its lower edge water sealed in an annular trough, with escape and admission valves to prevent the bell rising too high or falling too low.

The first plant in this country to supply the modern type of turbines. The turbine runs at 3,000 r.p.m., and drives an alternator delivering current at 3,000 volts. The maximum continuous output with high-pressure steam is about 900 kw., and the set has an overall length of 15 ft. 6 in. and a width of 6 ft.

Mention was also made in the Paper of an interesting scheme which is being developed in the North of England by Messrs. Merz & McLellan for the group of power companies for whom they act as consultants. This scheme consists of purchasing the exhaust steam from ironworks and similar concerns to run low-pressure turbines located in small power stations adjacent to the works, the current being delivered into the network of mains in the north-east district, and the condensed steam being returned to the works.

Some further examples of installations in this country and America were described, including the plant at the power station of the Philadelphia Rapid Transit Company, where the introduction of exhaust-steam turbines has given the company nearly 20 per cent. more power, and, in addition, return about 3¾ per cent. on their cost.

The following particulars regarding the low-pressure turbine

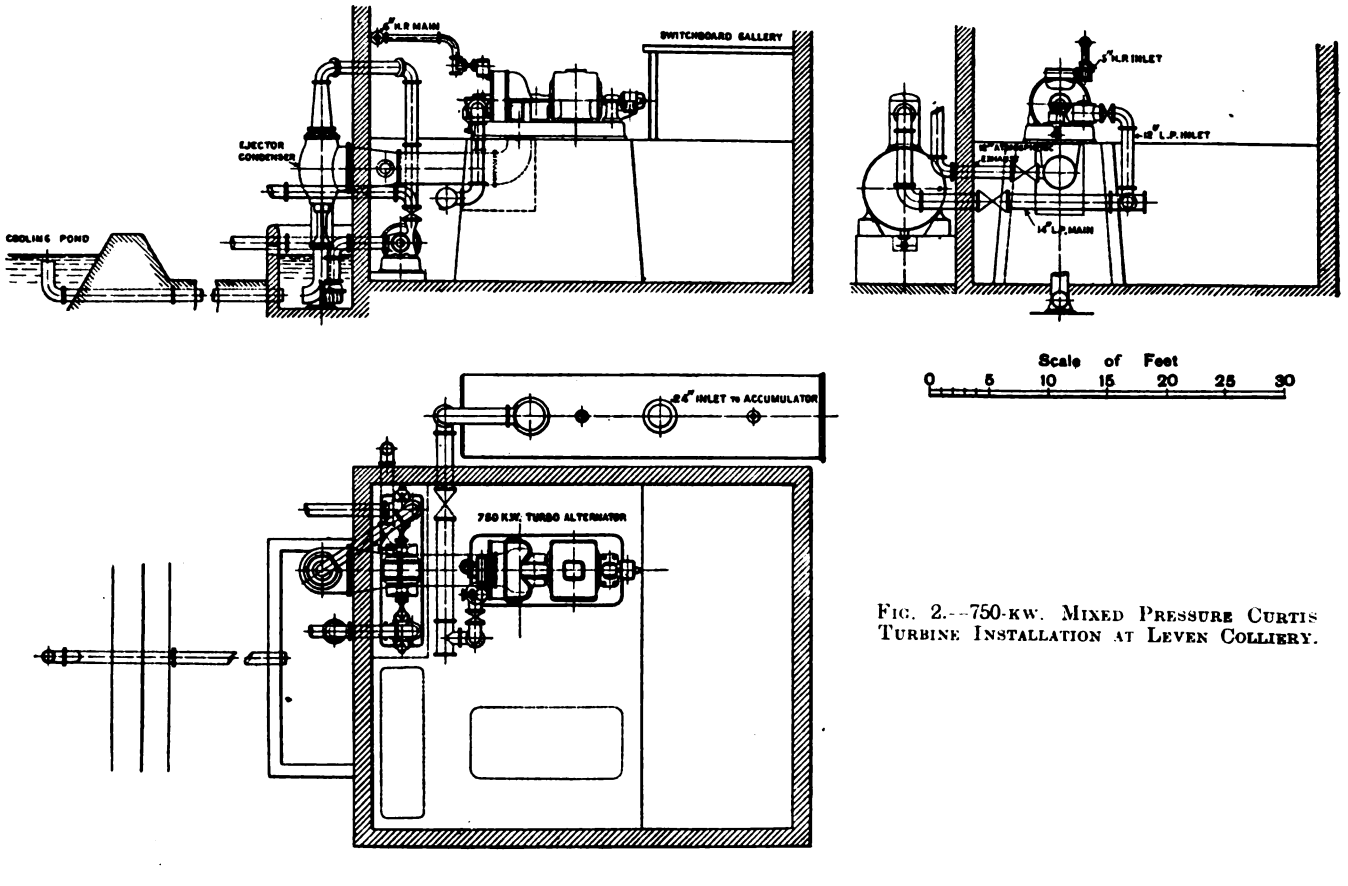

FIG. 2.—750-KW. MIXED PRESSURE CURTIS TURBINE INSTALLATION AT LEVEN COLLIERY.

Rateau accumulator was the Hallside works of the Steel Company of Scotland. This plant was installed in 1905 by Mr. P. J. Mitchell, the licensee for Rateau accumulators in this country, to whose energy is largely due the growing interest in exhaust steam utilisation. Steam is taken from cogging and finishing mill engines and two or three small engines and steam hammers, and is delivered into an accumulator 11 ft. 6 in. by 34 ft., the outlet from the accumulator being connected to two 450-kw. D.C. turbo-accumulators. In this way 900 kw. is obtained from steam which was formerly blown away into the atmosphere, as owing to the intermittent character of the load a satisfactory condensing plant would have been almost impossible to instal.

As an example of a mixed pressure installation, Fig. 2 shows the exhaust turbine plant now being supplied to the Leven Colliery of the Fife Coal Company by the British Thomson-Houston Co. through Messrs. Selby Bigge & Co., consulting engineers. At this colliery steam is collected from two winding engines, a fan engine, and several small pumps, and is delivered into a Rateau accumulator 7 ft. 6 in. by 30 ft. The amount of steam available for the turbine is only 16,000 lb. per hour, sufficient for about 400 kw., and since the maximum normal load on the turbine is 750 kw., the requisite amount of high-pressure steam to produce the additional load is admitted through groups of nozzles as in ordinary Curtis high-pressure plant which has been installed for the Edinburgh Corporation show that an even greater saving may be expected where the reciprocating engines are not so economical. In this station there are eight Willans & Belliss engines, each of 1,200 i.h.p., originally intended to operate with 25 in. vacuum, but always run non-condensing owing to lack of water. To deal with the exhaust from four engines, two Rateau turbines, running at 1,250 r.p.m., and coupled to Brown-Boveri D.C. generators at 490/550 volts, have been put down, each capable, when supplied with 45,000 lb. of steam per hour, the amount available from two engines at full load, of developing 1,250 kw. The two engines have a total output of 1,500 kw., consequently the increased output, without deducting the power required for auxiliaries, is no less than 80 per cent. The steam is admitted to the turbines at atmospheric pressure, the condenser pressure being 1·6 lb. absolute. The condensers are of the contra-flow type made by Messrs. Richardson, Westgarth & Co., and it is interesting to note that owing to the absence of any water it has been necessary to use sewage for circulating purposes.

Another example of a large American exhaust-steam turbine installation is a 5,000 h.p. vertical Curtis turbine in the power-house of the Rapid Transit Co. of New York, which is said to result in a saving of 93 tons of coal per day, sufficient, with the prevailing cost of coal in New York, to pay for the whole cost of the turbine in little more than one year.

THE WIRELESS TELEGRAPH STATIONS OF THE EIFFEL TOWER

THE concluding article of a series which has recently appeared in *Le Genie Civil* gives a description of the various wireless telegraph installations which have been constructed and are projected in connection with the Eiffel Tower in Paris. It has been long realised that the Eiffel Tower, from its height and situation, presented unique opportunities from a wireless telegraph point of view, but it is only comparatively recently that long-distance communication has been carried out from it.

One of the first experimental installations of any importance was a small equipment constructed in 1905 by M. Eiffel, which was placed at the disposal of Captain Ferrié. Communication was established from this installation to distances ranging up to nearly 250 miles. At first the single aerial wire which was used was suspended from the second platform of the tower, but later, as the distances experimented with became longer, the upper end of the wire was attached to an ebonite insulator near the summit, and the lower end of the wire taken to a hut on the ground at some distance from the tower. With this arrangement communication was successfully carried out in 1905 with Belfort. The influence of the larger metallic mass of the tower, however, prevented such good results being obtained as might have been expected, considering only the height of the aerial. An alteration in the anchoring of the lower end of the wire improved matters, and the arrangement shown in Fig. 1 was adopted first, with the single wire pulled off further from the tower of the wire *AV* attached to an insulator *i*, and a conducting wire leading down to the hut *P*. Three wires

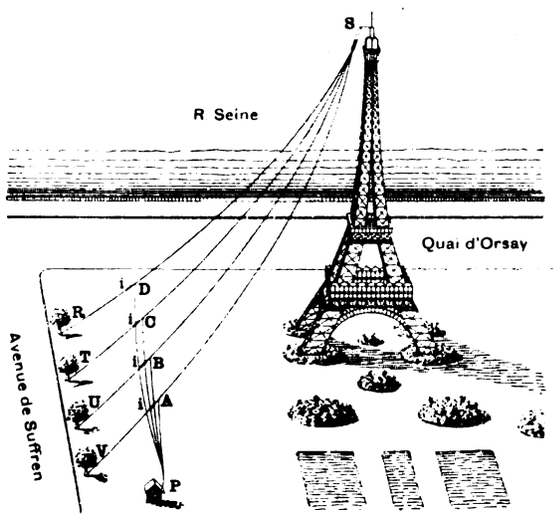

FIG. 1.—ARRANGEMENT OF TEMPORARY INSTALLATION.

more fixed in a similar way were afterwards added, as shown in Fig. 1. In the earlier experiments direct excitation of the antenna was employed, but an improved arrangement with a transformer was afterwards used. With this installation, temporary as was the nature of all the apparatus, communication was carried out at night with ships at distances of about 1,500 miles, with an expenditure of only 10 kw. The actual apparatus was enclosed in a roughly-made hut, and other temporary buildings served for the accommodation of the staff. It was with this installation that the famous series of communications with French warships at Casa Blanca were carried on.

Power for working the station was supplied from the generating station of the "Secteur" of the left bank of the Seine, at 3,000 volts 42 cycles, and transformed down to 220 volts in a sub-station at the base of the tower, from which an overhead wire was taken to the apparatus hut. A diagram of connections of the system is given in Fig. 2. The supply current passes through the key *M* and a variable inductance *I* to a step-up transformer *B*, the secondary (*H*) of which is connected across the condenser *K*. The pressure at the terminals of the condenser reaches about 50,000 volts, and the currents dealt with by the key range up to 100 amperes. The arrangement of the oscillation circuits with its air transformer, which has one primary and one five secondary turns, is shown in the diagram. The spark-gap is between the two large zinc cylinders *O*. The condenser *K* has a capacity of about half a microfarad. The earth connection was made to plates of zinc with a total surface of 1.620 sq. ft. buried in the ground.

As has been seen in Fig. 1, the aerial consists of the four wires, *SAP*, *SBP*, *SCP*, *SDP*, held as far away from the tower as possible by the pull-off wires, *RD*, *TC*, &c., insulated by ebonite insulators *i* from the antennæ themselves, and attached to trees adjoining the Avenue Suffren. These are so placed that the distance between the points *A* and *D* is about 300 ft. The actual conductors forming the antennæ are steel cables 4 mm. in diameter, and are attached to a short projecting beam at the summit of the tower by a special form of porcelain insulator. The potential at the top of the antennæ is said to reach hundreds of thousands of volts, and a wave-length of 1,600 metres

is produced. Special arrangements are made for lowering the whole system to the ground in case of repairs or alterations.

The reception of messages is made, as a rule, telephonically by means of an electrolytic detector coupled inductively. Communication has been carried on with Poldhu, with Nauen (near Berlin), with Morocco, Algiers, and stations in various parts of France. Messages have also been picked up from the Transatlantic Marconi stations at Clifden (Ireland) and Glace Bay (Canada).

Following the success of this temporary installation, negotiations were entered into for the construction of a permanent station, and in the spring of this year an arrangement was arrived at between the War Office, the Paris Municipality, and the owners of the tower. The work has been commenced, and it is hoped that the new station will be in operation during the early part of next year. In view of the fact that the

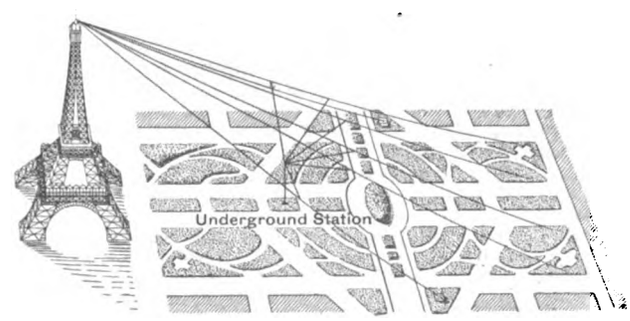

FIG. 3.—ARRANGEMENT OF PROJECTED PERMANENT INSTALLATION.

Champ de Mars is to be laid out as a public garden, and for other reasons, it was decided to put all the apparatus in an underground chamber instead of constructing a building above the surface. This will have the additional advantage of deadening the noise made by the apparatus. The projected arrangement of the aerial wires is shown in Fig. 3.

The underground station near the centre of the Champ de Mars will consist of a group of buildings surrounding a small sunk courtyard covered by a grille on a level with the ground

Digitized by Google

and reached by a staircase, the top of which will be hidden among vegetation. The supply of power, which, as the new station is to be much more powerful than the old installation, will reach over 100 h.p., and will be taken as before from the generating station of the Secteur de la Rive Gauche, but a stand-by supply from the machinery used for the lighting of the tower will also be available.

The antennæ will be composed of six steel cables from 4 to 6 mm. diameter, connected, as shown in Fig. 3, to a single cable, which passes vertically down to the underground court-yard. In view of the great tension on the wires, which amounts to about 6 tons in high winds, special care has been taken in their attachment at the top of the tower. Each wire is to be fixed by means of a substantial insulator to a special crossbar on the tower, and arrangements will be made so that any one wire can be lowered to the ground independently of the others. The pull-off wires will be anchored to concrete foundations. The two outside wires are anchored to short masonry towers in order to keep them a sufficient height above the carriage-way.

The wave-length will probably be 2,000 metres, and it is expected that communication will be possible over distances up to about 3,750 miles by day, and even further by night.

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY

MANY attempts have been made to bring in on a really commercial scale, electrolytic zincing. As a matter of fact there are several processes in limited operation, but it cannot be said that this method at all enters into competition with hot galvanising. Probably one of the chief reasons against the electrolytic process is to be traced to the appearance of the deposit. Hot galvanising gives a most artistic finish, owing to the large crystalline appearance of the coating of zinc. On the other hand, articles electrolytically coated have a matt-grey appearance, due to the fact that the deposited metal is in the form of very minute crystals; the best description of the coating is to say it appears to have been sand-blasted. In the *Electrochemische Zeitschrift* of December, Carl Richter describes a method by which he is able to obtain a bright deposit by electrolytic means. The bath employed is a modification of that of Pfannhauser, and consists of zinc sulphate and ammonium sulphate, but whereas that of Pfannhauser is employed neutral, Richter adds small quantities of sulphuric acid; the amount, however, is extremely small, varying from 1/38 to 1/20 normal. The temperature of the bath was usually kept at that of the atmosphere, a current density of about 80 amperes per square decimeter (about 740 amperes per square foot) was employed, the E.M.F. being between 0·75 and 0·85 volt. Electrolytic zincing has so much in its favour, at any rate for small articles, and for articles which require to be bent about, owing to the extremely adhesive condition of the zinc, that given a method for depositing it in a bright form, it should rapidly come in use on a large scale. One of the objections to hot galvanising is the large amount of spelter which requires to be kept in use, and the deterioration which takes place by alloying with the articles which are dipped, and the necessity to keep the bath molten meaning the employment of a large amount of fuel.

The Chemische Fabrik Griesheim-Elektron are arranging to erect a plant for storage of hydrogen for filling balloons. The gasometer is to have a capacity of 1,500 cubic meters, and the gas is to be obtained by electrolytic means.

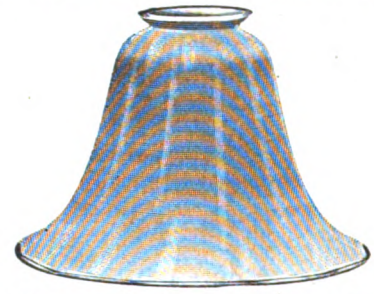
In the *Electrochemical and Metallurgical Industry* of December there is an interesting letter by Mr. R. H. Wolff, dealing with the electric furnace for rail and ordnance steel. Mr. Wolff considers that there would be much fewer flaws and faults in steel, such as were described by Mr. W. Rosenhain in his Paper before the British Association. The faults are generally attributable to traces of slag or of manganese sulphide becoming pocketed in the steel. Mr. Wolff points out that such faults rarely exist in crucible steel, but crucible steel is much too expensive for railway companies to purchase it for rails, but "with modern power-producing plants, hot metal from oxidising furnaces can be purified and deoxidised in a Héroult electric furnace in a short time, producing a very pure metal free from slag and other injurious bodies; in fact, a material equal to the best crucible steel, only more uniform, *at a reasonable extra cost over open-hearth steel.*" All, therefore, that is necessary in steel works, is to add a Héroult furnace equipment to the already existing Bessemer and open-hearth steel plants without any radical change whatsoever. Although quite in agreement with Mr. Wolff as to the high efficiency of the Héroult electric furnace, we would not necessarily confine ourselves to this particular form of furnace. For example, the new three-phase Roechling-Rodenhauser Electric Induction Furnaces are also extremely suitable for this class of work. There are also the Girod and Stassano electrode furnaces, which have given great satisfaction in the preparation of high-grade steels.

CATALOGUES AND PAMPHLETS RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering"].

RIVETED STEEL POLES.—A leaflet from Messrs. Francis Morton & Co., Ltd., of Hamilton Ironworks, Liverpool, and 17 Victoria Street, S.W., calls attention to the "Hamilton" pattern of riveted steel plates for telegraph arc lamps and other purposes, and a special type of channel steel insulator arm.

ELECTRIC FITTINGS AND GLASS WARE.—The latest edition of the General Electric Company's catalogue of fittings and shades is a most handsome and complete production. The opening accessory section contains a very full list of such small but important articles as cord grips, nozzles, hooks, ceiling plates, cord ornaments and shorteners, adapter ball fittings, and a host of other necessary appliances which only too often are but incompletely dealt with in such catalogues. In the succeeding portion many hundreds of illustrations of fittings are included dealing with every conceivable requirement, and ranging from the plainest workshop pendant to the massive ormolu and cut crystal electrolier. The illustrations give an excellent idea of the artistic nature of these productions, among which attention should be drawn to a beautiful series of French bronzes.



The section dealing with shades shows that a great deal of attention has been paid to shades and reflectors suitable for metal filament lamps, with long bulbs, and amongst the novelties we notice the two special reflecting shades illustrated above. In the first, the horizontal rays are reflected downwards by ribs in the glass. The second shade, although transparent, is finished inside with silver, which reflects the light very effectively.

POCKET-BOOKS, DIARIES, &c. for 1909.

THE annual pocket-book issued by Simplex Conduits, Ltd., forms, in addition to a pocket diary, a useful compendium of information on the well-known installation, material, &c., supplied by the firm.

Messrs. Venner & Co. are sending out a very artistic stamped metal table calendar for 1909, adorned with a representation of a hunting scene. The firm have adopted the novel course of omitting all advertising matter on the calendar itself in deference to the desires of some of their friends, who last year experienced difficulty in removing the advertisement, and finding a suitable picture to go in its place. We are asked to state that, owing to the breakage of a die, there may be a slight delay in completing the issue of these, but that all the firm's customers will be supplied by about the middle of January. Should any of our readers who are not already customers of the firm desire one of these calendars, they are requested to forward a shilling with their request.

The monthly tear-off calendar, which is being issued by the London electric firm of George Street, Croydon, is embellished with a number of illustrations of the various forms of arc-lamp lowering-gear which the firm specialise.

Flame Arc Lamp Electrodes.—Drops of melted material sometimes form on the ends of flame arc lamp carbons, and this causes flickering of the arc. To remedy this, it has been proposed to add a certain amount of silicon carbide to the impregnating material, which causes a covering of unfused silicon carbide to form on the carbon ends. According to the *Electrical World* of New York, an American patent for this has been granted to a Berlin inventor.

RESULTS OF CONTINENTAL EXPERIENCE WITH TURBO-GENERATORS

THE following notes are taken from a recent article in *La Lumière Electrique*, and deal with a number of replies received by Mr. Müller-Köhler from users of steam turbo-generators. These are classified by the author as follows :—(1) Sets of under 290 kw. (2) Sets between 300 and 590 kw. (3) Sets between 600 and 900 kw. (4) Sets between 1,000 and 2,400 kw. (5) Sets of over 3,000 kw.

Group (1) contains 13 turbo-dynamos, mostly of the Brown-Boveri-Parsons type, of which seven are direct-current machines running between 2,500 and 3,500 r.p.m. The steam pressure lies between 110 and 120 lb. sq. in. in most cases, while eight of the machines use steam superheated 65° to 130° C. (115° to 235° F.). About half the condensers are of the surface type. On the whole, the steam consumption of the machines in this class has been less than that guaranteed, being, on the average, 25·3 lb. per kw.-hr. using superheated steam, and 27·0 lb. per kw.-hr. using saturated steam. In one case the consumption fell to 19·1 lb. per kw.-hr. The annual oil consumption is from 140 to 440 lb. for the turbine alone, and from 770 to 1,000 lb. for the combination (turbine and dynamo). In general the overload capacity specified does not exceed 30 per cent. According to the replies given, in spite of the uninterrupted running imposed on the machines, mishaps are very rare. In most cases the repairs necessary have been *nil*, or very slight and cheaply effected; in two cases only have stripped blades been reported. For the 100-kw. class the cost of installation amounts to about £12 per kw. without condensers, and to £16 per kw. including condensers; for the 250-kw. class the cost of installation varies from £6·6 to £8·4 per kw. non-condensing, and from £10·4 to £12 per kw. with condensers. The figures given appear to refer to full load tests.

The replies received concerning the second group (300 to 590 kw.) include 22 installations, of which six are direct current, 14 three-phase alternating, and two single-phase alternating (high tension). In this group Parsons' turbines again predominate, 19 being installed, as against two of the Zoelly type and one by the Allgemeine Elektricität-Gesellschaft. Apart from a few exceptions the r.p.m. is 3,000. More than half (13) the turbines in this group use steam superheated from 41° to 150° C. (74° to 270° F.); the remaining nine use saturated steam. Two of the turbines utilise the exhaust steam from reciprocating engines at a pressure of 2·84 lb. per sq. in., while the other machines use steam at pressures varying from 105 to 185 lb. per sq. in. In twelve installations surface condensers are used, in nine jet condensers are employed, while the exhaust of one turbine is used for heating.

The steam consumption per kw. hr. is 22·0 to 24·2 lb. for the 300 to 385 kw. machines using superheated steam, and 24·5 to 25·0 lb. where saturated steam is employed. For the 400 to 550 kw. sizes the consumptions are, respectively, 19·7 to 22·0 lb. and 22·6 to 27·5 lb. per kw.-hr. This guaranteed consumption has not been attained during trial runs. In one case, using superheated steam, a consumption of only 18·7 lb. per kw.-hr. has been certified. The two exhaust turbines referred to consume respectively 38·3 and 39·2 lb. steam per kw.-hr. The turbine running non-condensing (with superheat 50° C. (90° F.) and pressure 190 lb. per sq. in.) consumes, on full load, 112 lb. steam per kw.-hr. The annual cost of lubrication of the turbines is £3 to £20·5, and the cost of cotton waste, &c., varies from 5s. to £5·2.

Overloads of 6 to 10 per cent. are common; one of the turbines ran continuously for one month on an overload of 34 per cent., the output then being 740 kw Although the majority of the turbines in this class have been running five years, no mishaps, beyond the most trivial, are reported. Three turbines have shown slight deterioration of the blading, the most serious of which caused shut-downs for 24 hours and 72 hours respectively. The maximum cost of repairs rose to £26 (for an admission valve). In eight cases accidents to the dynamos have been reported, usually in connection with the commutator and brush gear. In one case a turbine seized, in consequence of a defect in the main valve; the generator rotor was destroyed, but the turbine was not further injured. In this class the costs of installation varied from £6 to £10 per kw. for the turbo set, including the dynamo and exciter machine but without condenser. The cost of the latter varies from £6·2 to £12·8 per kw. Turbines working on the exhaust of reciprocating engines cost from £8 to £10 per kw.

(3) Machines from 600 to 900 kw. This group includes eight Parsons turbines and three Zoelly machines, of which eight drive three-phase alternators and three are coupled to direct-current generators. The speed is 3,000 r.p.m. for machines of less than 700 kw., and 1,500 r.p.m. for the others. Practically all these turbines work with superheated steam—the superheat being 70° to 140° C. (=126° to 252° F.). The steam pressure varies from 105 to 170 lb. per sq. in., and surface condensers are usually employed. On the average the steam consumption reported, again less than the guarantee value, varied from 21 lb. per kw.-hr. as maximum, to 17·5 lb. per kw.-hr. as minimum. The annual weight of lubricating oil per turbine varied from 460 lb. to 2,460 lb., the corresponding costs being £9 and £26 respectively. (These amounts include the oil necessary for dynamos and condenser plant.) In general the overload to be dealt with is 30 per cent., maintained during several hours.

In this class only six cases of trouble have been experienced; the most serious caused a stoppage of five days, and was due to broken blades, from an unknown cause, in a Parsons machine. In three cases only have slight derangements to the dynamos been reported. In the class 600 to 670 kw. the cost of installation amounts to from £6 to £6·6 per kw. without condensers, and from £7·4 to £8 per kw. with condensers. For machines from 750 to 900 kw. these costs are £4·2 to £4·4 without condensers to £7 to £7·2 with condensers.

Group (4) includes 15 machines from 1,000 to 2,400 kw., there being nine Parsons machines, four Zoelly, and two by the Allgemeine E.-G. With the exception of one single-phase set all the machines supply high-tension three-phase alternating current (2,000 to 6,000 volts). With two slight exceptions the speed is 1,500 r.p.m. Four of the turbines use saturated steam, while all the others use superheated steam—superheated 45° C. to 110° C. (=81° F. to 193° F.)—at 105 to 170 lb. per sq. in. pressure. In three cases jet condensers are used; in the other cases surface condensers are installed. The condensing water per hour varies from 12,500 to 26,100 cu. ft. On the installation trials the steam consumption was found to be less than guaranteed, actually being from 17·9 to 18·2 lb. per kw.-hr. for the machines of 1,800 to 2,000 kw. output. The annual consumption of lubricating oil varied between 2,100 and 5,500 lb. for the turbine and dynamo combined (annual costs being £40 to £55 respectively).

Overload specifications include 10 to 20 per cent. overload for several hours, and 32 per cent. overload for 20 minutes. There have been few derangements to the turbines and none at all to the dynamos in this class. The installation costs varied from £4·2 to £5·7 for the 1,000-kw. type, excluding condensers; including the latter raises the cost to £7·5 per kw. For the 1,100 to 1,200 kw. sizes the cost of installation was found to be £6·20 to £6·25 per kw., while for the 1,800 to 2,000 kw. class these costs were £6·90 to £7·04, condensers being included in both cases.

Under heading (5) only two installations are dealt with. Both machines are of 6,000 kw., and generate three-phase current at 5,500 volts. The speeds are 960 and 1,000 r.p.m. respectively. Steam is superheated by 300° C. (540° F.); one set is provided with an "ordinary" condenser (presumably of the jet type), while the other has a surface condenser. The cooling water per hour in the two cases is 63,400 cu. ft. and 71,900 cu. ft. respectively. The water temperatures are 5° C. and 25° C. at inlet and outlet respectively; one of these installations contains a water-cooler to deal with the air-pump discharge.

From actual trials the certified consumptions are :—14 lb. per kw.-hr. at full load (guarantee = 14·3 lb. per kw.-hr.); 14·8 lb. per kw.-hr. at half-load, and 15·65 lb. per kw.-hr. at ¼ full load. The consumption of oil by the turbine alone is stated to be "practically *nil*." One of these two machines has been overloaded daily to 7,500 kw. (25 per cent.). As for derangements, one has had damaged blades, while the condensing plant has given trouble in the other; the first damage caused a shut-down of nine days, though the repair cost little to effect; the repair to the condensing plant cost £21. The costs of installation amounted to about £3·84 and £4·28 per kw.-hr. respectively, this including turbine, dynamo and condensing apparatus.

M. Müller concludes by stating that all the owners of steam turbines, with the exception of a very small minority, give a glowing account of these machines. Hence as *résumé* of the replies received, one may conclude that both owners and engineers in charge of steam turbines are extraordinarily satisfied with this simple type of prime mover.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Dec. 24th, 1908

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.
Names in italics indicate communicators of inventions from abroad.

1907 Patent

27,132, **Arc Lamp.** BRITISH THOMSON-HOUSTON CO., LTD. (*Allgemeine Elektricitäts-Ges.*). In flame-arc lamps with inclined carbons which contain mineral matter, the slag which is formed on the carbon tips frequently prevents the arc from striking when the circuit is closed. According to this invention, a metallic bridge with a knife edge is arranged at right angles to the plane of the carbons so that, when the lamp is switched on, the carbons strike this bridge. Any slag on the carbons is then removed, and the bridge forms a conducting path between the carbons so as to assist in striking the arc. Two claims, one figure.

1908 Patents

1,751, **Petrol-electric Transmission System for Vehicles.** W. N. STEWART, E. B. KILLEN, and F. HARRIS. In this system of power-transmission for vehicles, the petrol engine is connected through a flexible coupling to the rotating field system of a "dynamotor," and can also, by means of a clutch, be connected to the armature; it is never in direct mechanical connection with the driving gear, however. At normal speed, the engine drives the field system in one direction, while the armature, which is then in mechanical connection with the driving gear, is driven in the opposite direction by means of a storage battery. On downward gradients, the speed of the armature increases so that it returns current to the battery, and when standing still, the armature is disconnected from the driving gear and driven direct by the engine for the purpose of recharging the battery. The field system is both shunt and series wound. The petrol supply is automatically controlled, and the throttle is mechanically connected to the clutch. Four claims, one figure.

5,199, **Cables.** H. GRAY. This specification describes a method of construction for stranded cables, which is said to prevent movements of the cable due to expansion or contraction of the strands. The conductor is so stranded that the wires in every layer do not form a complete sheath round the preceding core or layer. Spaces are thus left between the wires comprising each layer, which may or may not be filled with loosely packed material. Two claims, two figures.

5,415, **Manufacture of Metal Filaments.** BRITISH THOMSON-HOUSTON CO., LTD. (*General Electric Co., U.S.A.*). This invention relates to the production of filaments of pure zirconium or alloys of that metal. A squirting solution of zirconium oxalate (which is itself gelatinous in nature), is prepared by precipitation of hot zirconium nitrate solution with ammonium oxalate. Sufficient powdered carbon is then mixed with this to combine with the whole of the residual oxygen of the oxalate during the heat treatment. The absence of pitch or other carbonaceous binder ensures freedom from volatile hydrocarbons in the furnace, and consequently a filament entirely free from carbon is produced. In the case of filaments of an alloy of zirconium, the gelatinous zirconium oxalate forms the only binding agent for the mixture. Three claims.

6,960, **Alternating Current Commutator Motor.** BRITISH THOMSON-HOUSTON CO., LTD. (*General Electric Co., U.S.A.*). Commutator motors in which both inducing and exciting windings are arranged on the stator, may be started with the armature short-circuited, and, for high speeds, have a shunt voltage impressed on the armature to reduce the strength of the inducing field which has an injurious effect on commutation at high speeds. It may happen that the armature ampere-turns exceed the inducing ampere-turns in the latter case, and the object of the present invention is to prevent this from having a bad effect on the commutation, by arranging the inducing winding so that it is concentrated near the pole tips, where commutation occurs. Five claims, five figures.

17,410, **Switches.** A. P. LUNDBERG, G. C. LUNDBERG, AND P. A. LUNDBERG. This specification relates to that type of switch in which the contact-carrying arm is mounted on two independent pivot pins, and in which the actuating spring, which engages at one end with one of the pivots, and at the other end with a pin that works in a slot in the arm, holds the arm in either of its end positions. Two designs are described in the specification, one with a double-acting tumbler arrangement, and one with two press-buttons. Two claims, fifteen figures.

17,417, **Method of Cooling Commutators.** SIEMENS BROTHERS' DYNAMO WORKS, LTD. (*Siemens-Schuckertwerke*). A special construction of commutator is described in this specification. The bars are of the usual dovetail shape, and are held by clamping rings at either end, but a hollow space is provided between the bars and the hub, and a fan-shaped construction is arranged at one end to ensure a strong draught of air through this annular passage. Plates are let into the under surface of the bars and project into the air space, thus offering a large cooling surface. Two claims, four figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.
Names in italics indicate communicators of inventions from abroad.
Summaries of some of the more important of these patents will appear in our next issue.

1907 Patents

26,294, HARRISON. Means of supporting filaments in electric lamps.
27,034, DAVY. Arc lamps.
27,038, BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*). Motor-starting devices.
27,095, RYAN. Electrical welding-machines.
27,140, HAILWOOD. Ignition of miners' safety lamps.
27,559, MURPHY. Electrode for use in the purification of water.
27,632, ERICSSON. Prepayment meter.
27,675, HATFIELD. Electromagnetically-operated apparatus.
27,682, AYLEN. Portable electric burglar alarm.
27,830, GIBBS. Electrolytic cells.

1908 Patents

2,153, BUCKTON. Incandescent lamp caps.
4,372, FELTEN & GUILLEAUME-LAHMEYERWERKE AKT.-GES. Regulation of the pressure of electrical machines.
6,520, DARNLEY. Attachments for telephone mouthpieces.
7,328, ALLGEMEINE ELEKTRICITÄTS-GES. Arc lamps.
8,427, COLLIS. Reflectors for portable lamps.
12,682, ALLGEMEINE ELEKTRICITÄTS-GES. Arc lamps.
13,136, SCHULZE. Measuring instruments having an electromagnetic brake.
13,539, HAACK. Mercury vapour lamp.
13,893, CHAMBERLIN & HARRINGTON. Points for tramways.
14,259, DIAZ & AZAROLA Y GRESILLON. Apparatus for preventing the theft of electrical energy.
14,332, VAN DEN BOSSCHE & VAN DEN BOSSCHE. Railway signalling systems.
14,538, BERG. Turbo-electric generator systems.
14,554, ALLMAN & LEESON. Electric vulcanising apparatus.
14,776, SCHWENKE. Automatic electric projectile igniters operated by admission of water.
15,376, RAINS. Electrical water-heaters.
15,818, AITKEN. Telephone cordless switchboards.
15,949, RORKE & RORKE. Make-and-break devices
16,910, SCHATTNER & AMBERTON. Prepayment meters.
17,336, EISIG. Method of securing tramway rails.
19,311, SIEMENS & HALSKE AKT.-GES. Manufacture of incandescence bodies of tungsten.
24,414, HAILWOOD. Apparatus for igniting miners' safety-lamps.
25,596, HAILWOOD. Apparatus for igniting miners' safety lamps.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

1908 Patents

17,611, SIEMENS & HALSKE AKT.-GES. Process for improving the ductility of tungsten.
26,120, JACKSON. Electrical distribution systems.
26,502, WANDREY. Electric shutter indicators.

Expiring Patents

The following patents expire during the current week after a life of fourteen years:—

148, of January 2nd, 1895. **Induction Instruments and Meters.** O. B. SHALLENBERGER. This specification covers an application of the induction principle to alternating-current instruments, and describes indicating instruments and meters in which a metal disc is acted upon by two coils. One of these carries the main current, and the other a current proportional to and in quadrature with the impressed E.M.F. The movement of the disc is retarded by a magnetic field.

437, a, of January 7th, 1895. **Enclosed Arc Lamp.** J. B. BARTON. (*W. Jandus.*) This patent relates to the method of prolonging the burning life of arc-lamp carbons by enclosing them in a nearly gas-tight chamber, thus causing the arc to be formed in an atmosphere of CO. It is not the Jandus master patent, over which there was a law case a few years ago, but a later patent covering a special construction of globe with inner and outer chambers.

ELECTRIFICATION OF THE VICTORIAN RAILWAYS

Adverse Report by the Commissioners

ACCORDING to the *Australian Mining Standard*, the report of the Victorian Railway Commissioners (Messrs. Thos. Tait, chairman, W. Fitzpatrick, and C. Hudson) on the report made by Mr. C. H. Merz upon the application of electric traction to the Melbourne suburban railway system (see ELECTRICAL ENGINEERING, September 24th, page 451) was presented to the Legislative Assembly during November. It will be remembered that Mr. Merz recommended the electrification of the Port Melbourne and St. Kilda lines to be undertaken first, and the other lines in three different stages. The Commissioners accepted his conclusion that the best system of electric traction to adopt for the lines was the direct current protected conductor rail system, working at 800 volts. The Commissioners also concurred as to the site of the power station and other technical details in Mr. Merz's proposed scheme.

After some remarks regarding the possibilities of increasing the effectiveness of the existing steam rolling stock, the Commissioners, however, regret that their examination of such of the estimates as they have been able to check shows that electrification would result in a considerably greater financial loss in all stages in the year 1912 than indicated by Mr. Merz in his report. The alterations in the estimates made by the Commissioners have not been submitted to Mr. Merz. The Commissioners make the estimated total capital expenditure required for electrification in excess of that required for continuance of steam working for the Port Melbourne and St. Kilda lines, and the interest charges, and the three different stages, as follows :—Port Melbourne, &c., £315,482, instead of £314,999; first stage, £687,628, instead of £651,935; second stage, £1,152,601, instead of £1,087,992; third stage, £1,801,460. Interest charges :—Port Melbourne, &c., £12,619, instead of £12,600; first stage, £27,505, instead of £26,077; second stage, £46,104, instead of £43,520; third stage, £72,058. Annual working expenses, including the antiquation fund—with electric traction—Port Melbourne, &c., £22,951, instead of £18,563; first stage, £83,567, instead of £73,571; second stage, £160,079, instead of £140,362; third stage, £251,625, instead of £219,700. With steam traction—Port Melbourne, &c., £149, instead of £4,537; first stage, £2,310, instead of £12,306; second stage, £18, instead of £19,735; third stage, £4,658 (loss), instead of £27,267.

The result of these alterations on the comparison of the increased cost of electric service with the increased revenue, due to improved facilities, in Mr. Merz's report, is to make considerable changes in Mr. Merz's figures for the actual percentage increase of revenue above the assumed normal growth of 20 per cent. necessary to balance the financial loss in the year 1912, as shown in the table opposite.

The amended figures in each case include provision for the antiquation fund, but do not provide for minor corrections or considerations.

After reviewing the proposed electric service, the Commissioners state that practically all the gain in traffic and revenue to be derived from electrification would be during what are known as the slack hours of the day, and "it would require a large increase during the slacker portions of the day, which it is estimated will be carried in 1912 with a steam service, to amount to a 5 per cent. increase on the whole traffic."

The Commissioners cannot see their way clear to conclude that the electrification of the railways is of sufficient importance or value to justify the incurrence of the large estimated capital expenditure, and the annual financial loss which it is estimated would be involved in the year 1912 by electrification.

	Mr. Merz's figures.	Amended figures.
Port Melbourne and St. Kilda Lines only	16·1 per cent.	25·0 per cent.
Stage I. of the electrification ...	6·2 ,,	11·3 ,,
,, II. ,, ,, ...	5·8 ,,	11·2 ,,
,, III. ,, ,, ...	7·8 ,,	13·3 ,,

The report concludes :—"We therefore beg to recommend—'That the electrification of the Melbourne suburban lines be not either in whole or in part undertaken at the present time'; 'That the financial results of the electrification of the Melbourne suburban lines, and the advantages which will be obtained by such electrification as compared with steam working, be reviewed at reasonable intervals, special consideration being given to the aspect of the likelihood of increased tramway competition'; 'That the possible ultimate electrification of those lines be always borne in mind in the rearrangement or provision of additional tracks, stations, engine-sheds, turn-tables, and other locomotive facilities, and, in fact, in connection with all alterations and additions, including rolling stock, which might be affected by electrification'; 'That additional steam locomotives be constructed as may be required from time to time to meet the increasing requirements of the suburban traffic—such locomotives in the event of future electrification being easily and cheaply convertible to engines for general service on country lines, where there will be for some time ample scope for the useful absorption of locomotives of this class'; 'That the work of lengthening and strengthening such of the existing bogie coaches as are suitable for the suburban traffic be proceeded with as fast as the finances will permit; such lengthened and strengthened coaches being suitable for electric traction, and permitting of the gradual withdrawal from the regular suburban service of most of the large number of small fixed wheel base stock now necessarily utilised in that service, and which can be used for holiday traffic, instead of seated and covered trucks'; and 'That the existing platforms be lengthened and the existing block sections be shortened as may be found necessary from time to time to provide for the safe and efficient movement of the traffic (an automatic or semi-automatic system to be adopted in shortening the block sections, provided such a system be found to be safe, efficient, and economical.)'"

LOCAL NOTES

ASTON: *The Tramway Question.*—Reviewing the work of the year, *The Birmingham Post* states that tramway matters have again engaged attention, and some important steps have been taken, with the result that most of the outstanding questions with the British Electric Traction Company, which involved claims amounting to between £12,000 and £15,000, have been settled. These claims, although independent of the actual reconstruction account, arose from the difficulties experienced at that period, the company claiming compensation for losses sustained owing to the alleged delay in the work of reconstruction. In May it was decided to allow the company to carry forward the sum of £10,000 in respect to losses incurred by them in working the tramways during the four years ended December 31st, 1907. Whilst the representatives of the Council were unable to admit the claim of the company that they were by law entitled to carry forward the losses, it was felt that as a matter of equity they had a strong claim for consideration. Moreover, it appeared to be the best solution of the difficulty in the interests of the ratepayers, for unless the terms had been agreed upon a most costly arbitration or litigation must inevitably have ensued. Under the arrangement the proportion of the capital expenditure upon which interest and sinking fund was to be charged to the company from January 1st was permanently settled at £200,000. At the same time, the company not only abandoned their claim to the disputed item of £13,693 (extras on No. 1 contract), but consented to the addition of the sum of £5,571 to the capital account, thus bringing up the total to the sum named, whilst various points in dispute respecting the amount to be paid to the Council for the purposes of a renewals fund and the price to be charged by the Council for electric current supplied for traction purposes were also settled. Since the fresh agreement was entered into tramway matters in the borough have been working smoothly, except in relation to the Perry Barr route, in respect of which friction still exists regarding fares and through running. This, however, is now a matter outside the jurisdiction of the Aston authorities.

Electricity Works.—During the year just ended extensions at the electricity works have been carried out at a cost of £33,000.

BARKING: *Electricity Charges.*—The Electricity Committee have decided in favour of the following scale of charges after January :—Up to 100 units per month, 2 1/2d. per unit; 101–1,000 units, 2d.; 1,001–3,000 units, 1 7/8d.; 3,001–4,000, 1 3/4d.; 4,001–5,000, 1 5/8d.; 5,001–6,000, 1 1/2d.; 6,001–7,000, 1 3/8d.; 7,001–8,000, 1 1/4d.; 8,001–10,000, 1 1/8d.; over 10,000, 1d.

COLCHESTER: *Boycott of Tramways.*—As the result of the Corporation raising the fares upon certain routes owing to the loss of £3,000 upon the tramway undertaking last year, the inhabitants are boycotting the cars, preferring to walk rather than pay the increased fares.

CONSTANTINOPLE: *Introduction of Telephones.*—The authorities are being urged not to work the proposed telephone system themselves, but to grant a concession to a company. At present there is a disposition to entrust the undertaking to the Ministry of Posts and Telegraphs, which is charged with being a long way behind European proficiency in its administration.

DEVONPORT: *Corporation and Tramways Co.*—The Devonport and District Tramways Co. have intimated to the Corporation their intention to discontinue running cars on certain of the leased lines on and after January 16th next, for the reason that the working of these lines is unremunerative. The Tramways Committee have referred the matter to the Town Clerk, who will report at a special meeting of the Committee, which will be held previously to the January meeting of the Council.

Digitized by Google

DUNDEE: *Charge for Tramway Current.*—The charge for energy made by the Lighting Committee for tramway purposes was under discussion at the last meeting of the Council. The allegation is that it is being supplied at less than cost, viz., 1·5d. per unit up to 200,000 units and 1d. per unit for all energy over that amount, whereas the total costs work out to 1·63d. per unit. After a lenthy discussion the matter was referred to the two committees for further consideration.

Accident at the New Electricity Works.—An accident, which, fortunately, was not attended with serious results, occurred last week on the construction work in connection with the new power station at Carolina Port. The erection of the pump chamber, which is situated at the north-east corner of the Fish Dock, has presented some difficulties. According to the *Dundee Advertiser*, it consists of a cylinder of reinforced concrete, the walls of which have a uniform thickness of 6 in. From above the cylinder is moulded, and by its own weight is sunk to the desired level. Work on it has been in progress for many weeks, and up till the other day the rate of descent was slow—not at all commensurate with the internal excavation. Suddenly, however, the mass of concrete coming upon what was in effect a quicksand suddenly descended a distance of nearly 4 ft. As a result there was an inrush of water. Five men at the moment were employed in the interior. Four of the workers made a rush for safety, ascending by means of the hoisting gear. The fifth was in a sense trapped, but was eventually rescued by the same means. At the time of the mishap the tide was high, hence the inrush of water. Having regard to the shifting nature of the soil, the pump chamber will require to be sunk to a lower level than was at first contemplated. At the moment its lower edge has attained a depth of about 32 ft. below the level of the made-up ground, but the pump chamber will now have to be sunk to the rock bottom.

DURBAN: *Electricity Report.*—The eleventh annual report for the year ending July 31st, 1908, of the Borough Electrical Engineer, Mr. John Roberts, says that the number of private consumers now amounts to 3,931, compared with 3,702 in the previous year The number of power users is 244 compared with 222 in the previous year. A scheme is outlined for the wiring and fitting of consumer's premises, on the basis of the consumer paying 4 per cent. interest on the capital outlay for three years.

FARNHAM: *Overhead Wires.*—A Board of Trade inquiry was conducted last week at the Council's offices into an application by the Farnham and District Electric Supply Co. for permission to erect overhead wires, the company having been granted an order in 1905. The Hon. T. H. W. Pelham presided, and was accompanied by Mr. A. P. Trotter, electrical adviser to the Board of Trade. It appeared from the proceedings that a petition signed by 437 ratepayers objecting to the erection of overhead wires has been sent to the Board of Trade, this number representing one-third of the ratepayers of the district. The Board of Trade consequently ordered a local inquiry. Without prejudicing the question in any sort of way, the Hon. T. H. W. Pelham pointed out that the general principle of the Board of Trade was not to give sanction for the overhead wires except in unpopulous places or in populous places where there was a great deal of waste land and moorland, as was the case very often in large manufacturing districts. There was a feeling in the country very much against overhead wires in populous places. They all knew that the overhead system was a great nuisance and annoyance in towns where there was a great deal of traffic. The onus lay on the company, because the feeling of the Board of Trade was rather against overhead wires for electric lighting purposes in an urban district or in a populous place. The case for the company was that the methods adopted for obtaining signatures to the petition were not all that could be desired, in many cases the wife of a ratepayer being allowed to sign for him in his absence, and in other cases the signature was not that of a ratepayer at all. The real question, it was pointed out, was whether electric light by means of overhead wires was better than no electric light at all, because the company could not afford to lay underground mains. It may be said that the Council itself is not opposed to overhead wires, the company having agreed to their conditions, and that the objections have been raised through a fear that the amenities of the district will be spoiled. The inquiry terminated, and a decision will be given later.

FRANCE: *The Electrical Industry.*—An American Consular report states that in the past few years very important changes have been made in the street-railway systems in and around Roubaix, as well as in connection with electric lighting. Large central stations have been installed and are now supplying mills, industrial establishments, cafés, private houses, and small workshops for light and for running machinery. Great attention should be given by those interested in this industry, as further changes are soon to take place and prospects for the sale of electrical supplies are extremely bright.

HASLEMERE: *Electricity Supply.*—The Special Committee appointed to consider the proposed application to the Board of Trade by the Hindhead & District Electric Light Co. for powers to extend their area to include Haslemere, Thursley, and Witley, have recommended that no objection be raised to the company extending to Haslemere, but that they should be asked to lay mains in streets other than those specified. The committee had had before them the terms of certain other places, and the price appeared usually to be 6d. per unit, and not 8d., as in this case, and the committee recommended that they should ask if the maximum price could not be 6d. per unit. There was a clause in the Order that, notwithstanding anything which appeared in the Order, the company should not be obliged to give a standard supply of current, or should not be obliged to give any current at all between sunrise and sunset. The committee recommended that the attention of the Board of Trade should be called to those conditions.

KIRKCALDY: *Proposed Tramway Extensions.*—The borough electrical engineer and tramways manager has reported upon the advisability of constructing a number of new tramways, including joining up with Dysart. The whole of the Council's statutory powers have now been exercised or have expired, and as the new lines proposed are not extensive, it is thought possible that the Council will not incur the expenditure necessary for promoting them. The matter is to receive further consideration.

LIMERICK: *Threatened Strike of Electricity Employees.*—The workers at the Corporation electricity works have threatened to strike unless a certain switchboard attendant is dismissed. The local Labour Council has taken the matter up, and in order to avoid trouble, the Corporation has decided to ask the man in question to resign.

LONDON: *London County Council. Tramways.*—The annual report of the Council contains particulars of the tramways undertaking. In their report, the Highways Committee state that all possible progress is being made with the electrification of the tramways, but that it is less rapid than formerly, because those lines of the narrower routes have been left to the last owing to the difficulties presented in regard to widenings.

Highgate Hill Cable Tramways.—It is announced that the London County Council will take over the Highgate Hill cable tramway undertaking on March 31st next, and will at once proceed with its conversion to electric traction.

Lighting of the Tower of London.—For some time past there has been an argument as to the legal rights of the City of London Electric Lighting Co. to supply the Tower of London, the Stepney Borough Council contending that the greater portion of the Tower, at any rate, came within their area. It is now stated that the company have decided to abandon the contest, and thus the threatened legal proceedings will not be taken. A supply of electrical energy will therefore be taken from the Stepney Borough Council.

LUCAN: *Proposed Extension of Electric Railway.*—The Judicial Committee of the Irish Privy Council has granted an order for an extension of the Dublin and Lucan electric railway to Leixlip.

MORECAMBE: *Electricity Works Staff.*—In consequence of the suggestion by the Electric Light Committee that the staff of the electricity works should be reduced, the Borough Electrical Engineer has informed the Committee that he will not be responsible for any mishap at the works through an insufficient staff.

Tramways Arbitration Adjourned.—The arbitration proceedings which have been going on in London in relation to the purchase of the horse tramways in the town by the Corporation have been adjourned until January 8th. The estimates of the value of the undertaking are about £9,500 by the Corporation expert, and £16,000 by the company's witnesses, who include Mr. Stephen Sellon.

NORTH SHIELDS: *Electric Railway Under the Tyne.*—The promoters of the electric railway under the Tyne between North and South Shields have placed a proposal before the North and South Shields Corporations to contribute £100,000 of the £200,000 which is necessary for constructing the railway. The intention is that the promoters should pay the interest and sinking fund charges upon the sum loaned.

NOTTINGHAM: *Death from Electric Shock.*—An inquest was held on Monday into the death of C. W. Thomson, who received a fatal electric shock in the power-house of the Moorgreen Colliery, Nottingham, a few days ago. The deceased was superintending the erection of the switchgear on behalf of the British Westinghouse Co., and appears to have touched some live metal in one of the cubicles at the back of the main switchboard. It was understood that he was working in the second cubicle where there was no live metal, but for some reason he appears to have gone into the next cubicle where the current was not cut off. Mr. R. Nelson, the Electrical Inspector of Mines to the Home Office, said that, in his opinion, the accident was due to momentary forgetfulness on the part of the deceased, and that no blame was attaching to anyone. At the same time, there appears to have been a certain laxity in the handling of the keys of the cubicle doors, for it should not have been possible for the deceased to have obtained possession of these without the knowledge of the man in charge of the switchboard. He, therefore, strongly recommended that definite rules should be drawn up in respect of the handling of the keys. The jury returned a verdict that the "deceased was accidentally killed by coming in contact with an electric terminal," and considered that the accident was due to some oversight on the part of the deceased himself.

PLYMOUTH: *Challenge by Gas Company.*—The Plymouth and Stonehouse Gas Light and Coke Co. have written to the Cor-

Digitized by Google

poration in reference to an instruction to the electrical engineer to bring up a report dealing with street illumination by electric light, with special arc lamps in prominent points in the centre of the town. The company ask for facilities for demonstrating what can be done with gas, offering at the same time to defray the expense of such a demonstration. The company add that they feel justified in making this application, inasmuch as all ratepayers in Plymouth who are gas consumers are partners in the undertaking. By their Act of Parliament, approximately nine-tenths of the profits made by the company, after paying 5 per cent. to the shareholders, go to the consumer. Consequently, they say, if by the substitution of electric light for gas in the public streets of Plymouth a loss of net revenue is made by the company to the extent of £100 or £500, the ratepayers who are gas consumers will have to pay about nine-tenths of that loss in the gas bills. The letter concludes with a suggestion that the spots in the town selected to be illuminated by electricity and gas respectively should be agreed upon by the borough electrical engineer and the gas company's engineer, and that some impartial expert, or persons, be instructed to investigate the respective cost to the ratepayers by each method of lighting.

PAIGNTON: *Electric Supply.*—The Paignton and District Electric Supply Co. put their works into operation on Christmas Eve. The plant consists of a "National" suction gas-producer and gas-engine, of approximately 100 h.p., and a Crompton belt-driven dynamo with storage battery. Fourteen Crompton-Blondel flame arc lamps have been installed for public lighting. A refuse destructor is now being constructed adjacent to the power station.

SOUTHEND: *Electricity Finances.*—The district auditor, in his report upon the electric lighting accounts, states that, as the Council have, in the current year, dealt with the machinery which it was necessary to supersede and placed the works in a thoroughly satisfactory condition, he was for the first time able to express a definite opinion as to the leading results of the undertaking; inasmuch, however, as the machinery has not in the past been properly maintained out of revenue, nor, in the alternative, have revenue allocations been made to a depreciation and obsolescence account, one year's results cannot properly be compared with another. The auditor states that, in his opinion, the net loss on the undertaking since its inception in the year ended March 31st, 1902, has been £10,511. The capital expenditure at March 31st last was £116,715 19s. 1d.

WIGAN: *Colliery Equipment.*—The Moss Hall Colliery Co. are now proceeding with the erection of a generating station at the Maypole Colliery, Abram, near Wigan.

YORK: *The Tramways Undertaking.*—The Tramways Committee have reported that by the terms of the agreement between the Corporation and the City of York Tramways Co. for the purchase of the company's undertaking, it was provided that the company should continue to run the existing tramways for a period of three months after the date of the granting of the Light Railways Order. The order was made on October 19th, 1908, and consequently the company's obligation to run the tramways will continue until January 19th next. The company have been asked whether they would continue to work the tramways for a further period, but no terms have been agreed upon up to the present. The committee have considered the question, and recommend that the Council should take over the tramways from the company on the date mentioned or on the date of the actual completion of the purchase of the undertaking, and to run the same under their own management. In the event of the Council deciding to do so, the committee further recommended that they be authorised to make all needful arrangements for that purpose.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Miscellaneous

AYR.—The extension of the tramway system to Hawkhill has been decided upon.

GRIMSBY.—The Corporation invite tenders for the supply of continuous-current motors and starting panels, sizes ¼ to 15 h.p. Particulars from Mr. W. A. Vignoles, Borough Electrical Engineer. (See an advertisement this week.)

ITALY.—The *Board of Trade Journal* calls attention to the good openings presented in Naples and South Italy generally for electrical appliances and insulating material, much of which is apparently intended for Italian warships.

LONDON: *Hammersmith.*—Schemes and tenders are invited for altering the lifts and fans, at present worked by continuous current, to work from single-phase alternating current. Firms tendering are to specify what allowance they would be prepared to make for the present transforming plant and continuous-current motors. Particulars from the Clerk to the Guardians, 206 Goldhawk Road, Shepherd's Bush, and tenders by January 19th.

OLDHAM.—The Tramways Committee invite tenders for the supply, delivery, and laying of feeder cables, feeder pillars, ducts, &c. Specifications, &c., from Mr. Lewis Slattery, the tramways manager (fee two guineas, returnable), and tenders to the Chairman of the Tramways Committee by January 6th.

ROUMANIA.—The municipal authorities of Bucharest contemplate the construction of a new series of tramways. A company is to be formed with a capital of about £600,000, of which £200,000 will be provided by the municipality.

RUSSIA.—A loan has been authorised to the Town Council of Pskoff for the construction of tramways to the value of £80,000.

SWITZERLAND.—A decree has been issued granting to the company controlling the electric railway from St. Gall to Trogen a concession for the construction and working of an electric railway (1) from Trogen to Heiden, with a branch from Kaien to Rehetobel, and (2) from Heiden to Walzenhausen. The decree will come into force on January 1st, 1909. The cost, says the *Board of Trade Journal*, of the two sections is estimated at 2,900,000 francs (£116,000).

M. Spillman, of Zoug, has been granted a twenty-four years' concession for the construction and working of a section of one-metre gauge electric railways which will run from (1) Zoug to Nidfurren and Oberägeri, (2) Zoug to Baar and Talacker, and (3) Nidfurren to Edlibach and Menzingen: The total length of line, we learn from the *Board of Trade Journal*, will be 22·950 kilometres, and in the estimated cost of the work, viz., 1,730,000 francs, 450,000 francs (£18,000) have been apportioned for rails, and 362,000 francs (£14,480) for rolling stock.

Generating Stations, Sub-stations, Mains, &c.

AUSTRIA HUNGARY.—The *Board of Trade Journal* states that an electric supply works will be erected at Villach.

BELGIUM.—Tenders will be received, says the *Board of Trade Journal*, at the offices of the "Compagnie de l'Exposition de Bruxelles, 1910," Rue des Douze-Apôtres 34, Brussels, until January 15th, in connection with the supply of the necessary electricity for the purposes of the Exhibition.

DOVER.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £5,000 in connection with an extension of the electricity supply to St. Margaret's.

ITALY.—The *Board of Trade Journal* states that the Prefecture of Milan has, by decrees dated respectively November 10th, 15th, and 17th, authorised work to be carried out by the following companies:—(1) "Società Lombarda" to erect an electric power installation in the township of Gallarate; (2) "Società Ellettrica di Vergiate" to equip and work an electric light and power installation in the township of Cerro Maggiore; (3) "Società Lombarda" to erect an electric light and power installation in the township of Castano and Arlano.

LONDON: *Islington.*—The London County Council has sanctioned the borrowing of £5,541 for extensions to the Council's electricity undertaking, and offers to lend this sum at £3 17s. 6d. per cent. per annum.

RUGBY.—Tenders are invited for 440 yards or more of three-core low-tension paper-insulated lead-covered cable. Particulars from the Clerk to the Council and tenders by January 4th.

YARDLEY.—The Council's consulting engineer is now preparing a report upon the introduction of electric supply into the district.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

Battersea.—The Guardians have decided to expend ten guineas on a report dealing with the adoption of electric lighting.

N.W.—Enlargement of Bell Lane School (750 places), Hendon. Architect, Mr. Wilson, Hendon Education Committee.

PROVINCES.

BARNSLEY.—The question of the electric lighting of the market is under consideration.

BIRMINGHAM.—Police station, Allison Street (£17,000). E. O. Smith, Town Clerk.

Fire station, Albion Street (£11,170). Architect, Thomas G. Price, Union Chambers, Temple Row.

CARDIFF.—Laboratory and art block at Canton Municipal Secondary School (£3,800) for Town Council.

CHELMSFORD.—Council School (£10,500). Architect, W. H. Pertwee, Bank Chambers, New Street.

CHICHESTER.—School (£10,000). Architect, F. Lobley, Guildhall, Chichester.

DARWEN.—Extension of Infectious Diseases' Hospital (£2,600). R. V. Smith, Surveyor to Town Council.

DROYLSDEN.—School (800 places). C. Hall, Surveyor to Urban District Council.

Digitized by Google

FOLKESTONE.—New Grammar School. A. M. Nicholls. Borough Engineer, Folkestone.

HEREFORD.—Additions to Corn Exchange. Architects, Groome & Bettington, Palace Chambers, King Street, Hereford.

HOUNSLOW.—Laundry, London Road. Architects, C. H. Samson, The Laurels, Taunton.

LLANELLY.—Alterations to Old Castle Inn for Buckley Brewery, Ltd. Architects, J. Davies & Son, Llanelly.

Rebuilding Boar's Head Inn for Buckley, Ltd. Architects, J. Davies & Son, Llanelly.

Rebuilding Bear Inn, Felinfoel, for Buckley Brewery, Ltd. Architects, J. Davies & Son, Llanelly.

LUTON (BEDS.).—Pumping station. S. F. L. Fox. Borough Engineer, Luton.

School (£1,000). Architects, Brown & Sons, 9 Castle Street, Luton.

MANCHESTER.—New lending library in Cheetham Hill Road. H. Price, City Architect.

MERTHYR.—Alterations, Temperance Hall, for the proprietors.

NEWCASTLE.—Proposed the Queen's Hall and Buildings, Northumberland Street. Architects, Graham & Hill, Newcastle.

NORWICH.—Alterations and additions to Guildhall. A. E. Collins, Engineer to Town Council.

STOURBRIDGE (WORCESTER). — School. Worcester County Council.

SURBITON.—Special subjects buildings for Surrey Education Committee. Secretary, Ramsay Nares, Kingston.

UXBRIDGE.—A Committee has been appointed for considering the need for more efficient lighting in the infirmary.

WOOLWICH.—Police station. J. Dixon Butler, Surveyor to Metropolitan Police, New Scotland Yard, S.W.

TENDERS RECEIVED AND ACCEPTED

ABERDEEN.—The following tenders have been accepted for the supply of stores to the electricity department:—D. Richmond & Sons, Glasgow, wrought iron; J. M'Adam & Sons, carting; Clyne Mitchell & Co., cast-iron work; Duthie Bros., ropes, &c.; J. Blaikie & Sons, brass, lead, &c.; Shirras, Laing & Co., tallow; Glegg & Thomson and Shirras, Laing & Co., ironmongery goods; G. Donald & Sons and Farquhar & Gill, paint, oil, glass, &c.; G. Gordon & Co., timber.

BLACKPOOL.—For the supply of coal for the electricity works 23 tenders were received, and that of Mr. C. Hindle, of Blackpool, for "Pearson & Knowles" Standish Arley rough slack to the amount of 5,000 tons was accepted. The balance of next year's requirements has been left over until the Electrical Engineer has made tests on two or three selected fuels.

CARDIFF.—The Corporation have accepted the tender of Messrs. Willans & Robinson for a 2,500-kw. Willans-Siemens turbo-alternator.

GLASGOW.—The Corporation have accepted the tenders of Bryden & Middleton for an ash chut at Pinkston; Alexander Jack & Co., travelling crane at the new sub-station; the National Conduit & Cable Co., Ltd., trolley wire; and Siemens Bros. Dynamo Works, Ltd., dry cells.

LONDON: *City of London Gardens.*—An order has been placed with Pinching & Walton for 1 gross 16-c.p. lamps at £5 5s.; ½ gross 8-c.p. ditto at £2 12s. 6d.; ¼ gross 25-c.p. ditto at £1 6s. 3d.; ¼ gross 32-c.p. ditto at £1 9s. 3d.; and 1 dozen Osram lamps, £2 8s.

Marylebone.—The Council have renewed the contract for the maintenance of the Aron wattmeters used at the generating station with the Aron Meter Co. for a further period of twelve months at £28.

MERTON.—The District Council, upon the recommendation of the Fire Brigade Committee, have decided to adopt the "Gamewell" system of fire alarms, which the Post Office authorities are to supply and maintain for ten years at an annual rental of £66.

WATFORD.—The tender for the construction of the terminal station at Watford of the new Euston to Watford Electric Railway has been placed by the London and North Western Railway Co. with a local firm of builders, viz., Messrs. C. Brightman and Sons. It is expected that the work, which will be put in hand immediately, will be completed by January, 1910.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 65 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £66 to £66 10s. (Last week, £65 to £65 10s.)

CHANGE OF ADDRESS.—Messrs. Pritchetts & Gold, Ltd., inform us that, owing to the large and continued increase in their business, they are removing their sales department to larger premises at No. 58 Victoria Street, S.W., and all orders and correspondence with reference to that department should be sent to that address on and after the 29th inst. Telegraphic address and telephone numbers will remain unaltered.

DISSOLUTIONS OF PARTNERSHIP.—Sir Home Gordon, Bart., has retired from the firm of Messrs. Buchan & Partners, consulting electrical and mechanical engineers, Parliament Chambers, Westminster, London, and 16 Rutland Square, Edinburgh. The business will be continued as before by the remaining partners, Messrs. M. Buchan and R. W. Hogarth.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A meeting of creditors of the Buenos Ayres Electric Tramways Co. [1901] (in voluntary liquidation) will be held at the company's offices, 62 London Wall, London, E.C., on January 7th, at 12 noon. Notice is also given that all claims should be sent in not later than February 1st.

The statement of accounts in the bankruptcy of Messrs. Marten & Jellicoe, Ltd., Sumner Road, Thames Ditton, electrical engineers, &c., shows that the gross liabilities amount to £6,588 8s. 1d., of which £5.026 17s. 5d. is unsecured, and assets estimated at £1,358 12s. 7d., the whole of which is absorbed by debentures. The cause of the company's failure is said by the directors to be lack of sufficient working capital.

The Eldon Electric Co. is to be wound up voluntarily. Mr. William Sparks, of Newcastle, has been appointed liquidator.

MISCELLANEOUS CITY NOTES

HALIFAX AND BERMUDAS CABLE CO.—An interim dividend of five per cent. per annum, free of tax, for the past half-year, has been declared.

MELBOURNE TRAMWAY & OMNIBUS CO.—Cable advices have been received of the declaration of a dividend of 4½d. per share for the quarter ending December 31st, equal to 15 per cent. per annum.

SHAWINIGAN WATER & POWER CO.—Cable advices state that the earnings for November were $58,100 against $54,500 for the corresponding month of last year.

SOUTH LONDON ELECTRIC SUPPLY CORPORATION.—Letters of allotment for the issue of £100,000 5 per cent. first mortgage debenture stock have been posted.

Dissipation of Fog by Electricity.—With reference to the statements recently made that the Westminster City Council had granted facilities for experimenting with Sir Oliver Lodge's system of dissipating fog by electricity, Sir Oliver has written to *The Times*, pointing out that the publication of this fact was without his knowledge or consent. He would have preferred silence until after a large-scale experiment had been tried—if it was going to be tried. But even as to this he had no information. Sir Oliver Lodge takes the opportunity, however, of stating his connection with this subject as follows:—In the year 1884 I observed, and exhibited to the British Association, then meeting in Montreal, the extraordinary clarifying action of a high-tension electric discharge on fog or mist or smoke produced in a bell jar and electrified by a point. The particles of smoke coagulate, as iron-filings do near a magnet; they form themselves into large aggregates—clusters, flakes, or streamers—and then either fall or cling to the walls of the vessel. In a few seconds the space is clear, and the sides thickly covered with deposit. The nature of the smoke is immaterial; and a cloud of steam is by the same agency converted into Scotch mist or fine rain. I thought at the time that this was a new, though small, discovery; but, subsequently, I ascertained that something of the same sort had been observed by a Mr. Guitard long ago, and published by him in a short paragraph in the *Mechanics' Magazine* for 1850, this paragraph being referred to in that most industrious compilation, the late Professor Gustav Wiedemann's 'Galvanismus und Elektromagnetismus.' . . . I also tried it on a rather larger scale - clearing a cellar of turpentine smoke, for instance, and erecting an arrangement at Liverpool on the roof of the old University College there for applying a discharge of electricity to the open air." In a later paragraph Sir Oliver Lodge says:—"I have never regarded electrification as the ideal method for removing the incubus of town fogs These artificial nuisances ought not to be manufactured; improved methods of combustion are the way to reduce them. But in certain important local centres, such as railway stations and harbours, it may be worth while to experiment on the electrical method of clearing. Accordingly, when a few years ago the engineer to the Westminster City Council approached me with an inquiry, I said that I was willing to help. And when a year or so ago Mr. Walford called and said that he would like to put down money to try on a fairly large scale, I again expressed readiness if I thought the conditions hopeful. Since then I have heard no more. . . . If I see any reasonable hope of success in any scheme that is independently mooted—whether for influencing the weather or for clearing local fog—I will do what I can in my scanty leisure to help with advice, and may be able to relegate one of my assistants to the job."

NEW COMPANIES

DENNISON, KETT & CO.—This company was registered on December 19th, with a capital of £3,000 in £1 shares, to carry on the business of mechanical and electrical engineers and contractors carried on at 11 Queen Victoria Street, E.C., and 61–3 Lant Street, S.E., as "Dennison, Kett & Co." The subscribers are:—E. W. Dennison, Fairmead, Grove Park, Kent; F. Stur, 62 Sandrock Road, Lewisham, S.E., engineer; F. S. Stephens, 49 Queen Victoria Street, E.C.; G. Kett, 108 Gordon Road, Peckham Rye, S.E., engineer; H. G. Stimson, 10 Moorgate Street, E.C. Private company. The number of directors is not to be less than two nor more than five. E. W. Dennison is one of the first, and may retain office while holding £100 shares. Registered office: 11 Queen Victoria Street, E.C.

RESIDE & CO.—This company was registered on December 22nd, with a capital of £3,000 in £1 shares, to acquire the business carried on by Reside & Co., to adopt an agreement with J. Reside and W. Barraclough, and to carry on at Brighouse and elsewhere the business of electrical, mechanical and motor engineers, millwrights, tool makers, ironmongers, general merchants, &c. The subscribers are:—J. Reside, Close Lea, Rastrick, Brighouse, engineer; W. Barraclough, Bankfield, Raynor Road, Brighouse, engineer; H. T. Whiteley, The Rookeries, Old Lane, Brighouse. Private company. The number of directors is not to be less than two nor more than five; the first are J. Reside, W. Barraclough, and H. T. Whiteley. Qualification £10. Registered office: Perseverance Works, Huddersfield Road, Brighouse, Yorks.

A. L. M. SYND.—This company was registered on December 23rd, with a capital of £100 in 1s. shares, to acquire and dispose of the English and German patents in connection with the process for the manufacture of flexible aluminium foil, with a view thereto to take over the benefit of two contracts (1) dated November 4th, 1908, and made between Aluminiumfabrik Gontenschweil A.G. of the one part, and A. J. Faulding of the other part, and (2) dated November 3rd, 1908, and made between A. J. Faulding and others of the one part, and the Aluminium Corporation, Ltd., of the other part, and to carry on the business of aluminium foil manufacturers, &c. Private company. The number of directors is not to be less than three nor more than ten; the first are A. J. Faulding, J. W. Sidley, and J. Leemann-Abderhalden. Registered by A. O. Warren, 2 Broad Street Place, E.C.

THOMAS TRANSMISSION.—This company was registered on December 11th, with a capital of £5,000 in £1 shares, to acquire from J. G. P. Thomas a British patent relating to an electro-mechanical power transmission system, to turn the same to account, and to carry on the business of manufacturers of and dealers in motor-cars and vehicles, electrical and mechanical engineers, &c. The subscribers are: W. A. Tritton, 43 Anson Road, N., engineer; H. J. Thomson, 121 West Parade, Lincoln, engineer. Private company. The number of directors is not to be less than three nor more than seven; the first are W. A. Tritton, H. J. Thomson, and A. R. Mitchell, of 3 Balfour Road, Walmer, Kent. Registered office: Monson Chambers, Corporation Street, Lincoln.

TRANSVAAL HYDRAULIC POWER SYNDICATE.—This company was registered on December 12th, with a capital of £20,000 in £1 shares (15,000 "A" and 5,000 "B"), to exploit and investigate water power in the Transvaal and elsewhere, to pay preliminary, engineering, and other fees and expenses in connection with the acquisition of any option contracts, rights, and benefits, and to take over from the Transvaal Power Development Syndicate, Ltd., or others, contracts, rights, options, agreements, privileges, and benefits, to carry on the business of electricians and mechanical engineers, &c. Private company. The number of directors is not to be less than two, nor more than seven; the subscribers are to appoint the first. Qualification, 500 shares. Registered offices, 24 Coleman Street, E.C.

"Black" Smoke Prosecution.—At the South-West London Police Court last week the County of London Electric Supply Co. were summoned for contravening a prohibition order requiring them to abate a nuisance arising from the issue of "black" smoke from the chimney-shaft of their Wandsworth power-house. On behalf of the company, it was stated that the sum of £2.000 has been spent on smoke-consuming appliances, but that the issue of "black" smoke was unavoidable at times. In the present instance the smoke lasted about five or six minutes. A penalty of twenty shillings was imposed, the maximum penalty being forty shillings per day whilst the nuisance lasts.

Telegraph Traffic.—An interruption of the submarine cable between Medan and Penang occurred on the 22nd inst. Telegrams for Kotaradja and Sabang will be sent by telephone from Pangkalanbrandon, or by post from Penang. We are also able to announce the reopening to international telegraphic communication of the offices in Hayti, which were closed during the recent revolution. Owing to the terrific earthquake in Italy, communication with Messina is cut off. The lines of the Indo-European Telegraph Company between Tiflis and Tauris were also down on the 29th inst., but were repaired on the same day.

COMPANY MORTGAGES

VERITY'S.—A memorandum of satisfaction in full of debentures, dated January 9th, 1906, securing £40,000, has been filed. Particulars of £60,000 debentures, created by resolution of October 27th and secured by a trust deed dated October 31st, 1908, have also been filed pursuant to Section 10 (3) of the Companies Act, 1907, the whole amount being now issued. The above-mentioned trust deed has also been registered. Property charged—manufactory, warehouse, and premises at Aston, known as the Plume Works, works and premises at Plume Street, known as the Victoria Works, wharf and other buildings in Plume Street aforesaid, and the company's other assets, present and future, including uncalled capital. Trustees, Trustees Executors and Securities Insurance Corporation, Ltd., Winchester House, Old Broad Street, E.C.

FLEETWOOD & DISTRICT ELECTRIC LIGHT & POWER SYNDICATE.—Charge, dated December 8th, 1908, to secure £1,125, and further sums not exceeding in all £1,700, created by receiver appointed on behalf of debenture holders. Property charged—assets and undertaking, ranking in priority to a trust deed dated October 31st, 1899. Holder—W. C. Johnson, Broadstone Farm, Coleman's Hatch, Sussex.

CITY OF OXFORD ELECTRIC TRAMWAYS.—Debenture, dated December 14th, 1908, to secure £15,000. Property charged—The company's undertaking and property, present and future, including uncalled capital. Holders: Lloyds Bank, Ltd.

Official Advertisements are charged at the rate of **9d.** per line (column width).

Small Prepaid Advertisements of Situations Vacant and Wanted, Plant for Sale or Wanted, &c., are inserted at the rate of **1/-** for the first 12 words and 1d. per word afterwards. Three insertions for the price of two. Advertisements can be received up till Wednesday morning first post.

Letters should be addressed to The Kilowatt Publishing Co., Ltd., 203–6, Temple Chambers, London, E.C.

ELECTRICALLY-DRIVEN AIR-COMPRESSING PLANT FOR SALE.

2 INGERSOLL-RAND Belt-Driven Air-Compressors. Capacity 2637 c. ft. free air per minute each machine.

2 ditto, ditto. Capacity 1414 c. ft. free air per minute each machine.

1 Ingersoll-Sergeant Belt-Driven Air-Compressor with automatic unloader. Capacity 285 c. ft. free air per minute.

1 Holman Compressor, Belt-Driven. Capacity 300 c. ft. free air per minute.

Electric Motors for driving above complete with starters, switches and fuses.

1 205-H.P. 400-volts Single-Phase Motor.

2 110-H.P. 400-volts D.C. Motors.

2 14-H.P. Electric Motor Hoists.

All above Machines are in excellent order.

Further details and prices from:—

The Tilbury Contracting & Dredging Co., Ltd.,
L.C.C. Sewer Works,
Tower Bridge Road, S.E.

COUNTY BOROUGH OF GRIMSBY.

THE CORPORATION are prepared to receive tenders for the supply of continuous current motors and starting panels, sizes ¼ to 15 H.P. Full particulars and specification on application from the undersigned. Last date for Tenders, January 16, 1909.

W. A. VIGNOLES, M.I.E.E.,
Borough Electrical Engineer.

Electricity Works,
Grimsby.

December 30th, 1908.

CABLE JOINTER wanted for Valencia. Must be good worker, under 30, and have thorough knowledge of high tension sleeve jointing. If satisfactory, permanency as foreman. State salary required and past experience to Box A 68, Electrical Engineering, 203, Temple Chambers, London, E.C.

WANTED, an Engineer having a practical acquaintance with modern electrical developments. Such engineers are in demand, and command large salaries. You can qualify at home, under experts, and by a unique system. Prospectus free, The British Correspondence School of Electrical Engineering, Dept. M., 36, Maiden Lane, Strand, London.
